This document contains information that is proprietary to Mentor Graphics Corporation. The original recipient of this document may duplicate this document in whole or in part for internal business purposes only, provided that this entire notice appears in all copies. In duplicating any part of this document, the recipient agrees to make every reasonable effort to prevent the unauthorized use and distribution of the proprietary information.

This document is for information and instruction purposes. Mentor Graphics reserves the right to make changes in specifications and other information contained in this publication without prior notice, and the reader should, in all cases, consult Mentor Graphics to determine whether any changes have been made.

The terms and conditions governing the sale and licensing of Mentor Graphics products are set forth in written agreements between Mentor Graphics and its customers. No representation or other affirmation of fact contained in this publication shall be deemed to be a warranty or give rise to any liability of Mentor Graphics whatsoever.

MENTOR GRAPHICS MAKES NO WARRANTY OF ANY KIND WITH REGARD TO THIS MATERIAL INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

MENTOR GRAPHICS SHALL NOT BE LIABLE FOR ANY INCIDENTAL, INDIRECT, SPECIAL, OR CONSEQUENTIAL DAMAGES WHATSOEVER (INCLUDING BUT NOT LIMITED TO LOST PROFITS) ARISING OUT OF OR RELATED TO THIS PUBLICATION OR THE INFORMATION CONTAINED IN IT, EVEN IF MENTOR GRAPHICS HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

U.S. GOVERNMENT LICENSE RIGHTS: The software and documentation were developed entirely at private expense and are commercial computer software and commercial computer software documentation within the meaning of the applicable acquisition regulations. Accordingly, pursuant to FAR 48 CFR 12.212 and DFARS 48 CFR 227.7202, use, duplication and disclosure by or for the U.S. Government or a U.S. Government subcontractor is subject solely to the terms and conditions set forth in the license agreement provided with the software, except for provisions which are contrary to applicable mandatory federal laws.

TRADEMARKS: The trademarks, logos and service marks ("Marks") used herein are the property of Mentor Graphics Corporation or other parties. No one is permitted to use these Marks without the prior written consent of Mentor Graphics or the owner of the Mark, as applicable. The use herein of a third-party Mark is not an attempt to indicate Mentor Graphics as a source of a product, but is intended to indicate a product from, or associated with, a particular third party. A current list of Mentor Graphics' trademarks may be viewed at: www.mentor.com/trademarks.

The registered trademark Linux® is used pursuant to a sublicense from LMI, the exclusive licensee of Linus Torvalds, owner of the mark on a world-wide basis.

Chapter 1
Introduction

This manual describes the application commands for Tessent Shell, as well as the following products: Tessent FastScan, Tessent TestKompress, Tessent Diagnosis, Tessent IJTAG, Tessent DesignEditor, and Tessent Scan (formerly DFTAdvisor).

- Tessent FastScan is a comprehensive combinational Automatic Test Pattern Generation (ATPG) system optimized for full-scan designs. It offers high speed and accurately measured high test coverage to guarantee your product quality and reliability.
- Tessent TestKompress uses patented scan EDT™ (Embedded Deterministic Test) technology and many of the industry leading ATPG features of Tessent FastScan, to reduce scan data volume and test time by many times over Tessent FastScan ATPG. It is for users who need greater reductions in ATE memory and time requirements than are available with any other full-scan ATPG tool.
- Tessent Diagnosis is a sophisticated diagnosis tool used at different stages of test to help characterize and locate defects in manufactured chips. It is for users who need to shorten the time it takes to perform yield ramp, yield learning and customer return analysis. The unique advanced diagnosis capabilities it provides are also available in Tessent TestKompress.
- Tessent IJTAG is Mentor Graphics implementation of the IEEE P1687 (IJTAG) and supports reading Instrument Connectivity Language (ICL), performing automatic retargeting of IJTAG-specific PDL commands such as iWrite and iRead, and writing out the retargeted PDL patterns in many different ATE tester specific formats and as Verilog HDL simulation test benches. See the *Tessent IJTAG User's Manual* for complete information.
- Tessent DesignEditor is a less expensive product that provides access only to design introspection and editing features. This product only provides access to the dft context (commands labeled "dft" or "all contexts").
- Tessent Scan is the Mentor Graphics internal scan synthesis tool that identifies and inserts scan and test circuitry into your design. For more information, refer to the *Tessent Scan and ATPG User's Manual.*
- DFTVisualizer which is built in to all of these tools is a schematic and data viewing utility. DFTVisualizer adds the ability to graphically investigate and interact with designs, making it easier to debug problems. For more information, see "DFTVisualizer" in the *Tessent Shell User's Manual*.

In Tessent Shell, the term “context” refers to a broad category of functionality that often corresponds to a specific product and a license feature, such as Tessent FastScan. By setting the context, you indicate the type of task you want Tessent Shell to perform.

Table 1-1 lists the Tessent products supported by this manual and shows how they map to Tessent Shell contexts. For more information about Tessent Shell contexts, refer to the “Context and System Modes” section in the *Tessent Shell User’s Manual*.

Table 1-1. Tessent Point Tools

Product or Tool	Tessent Shell contexts	For more information
Tessent FastScan Tessent TestKompress (ATPG operations)	patterns -scan	See the “Generating Test Patterns” chapter in the *Tessent Scan and ATPG User’s Manual*.
Tessent TestKompress (IP insertion)	dft -edt	See the *Tessent TestKompress User’s Manual*.
Tessent IJTAG	patterns -ijtag	See the *Tessent IJTAG User’s Manual*.
Tessent DesignEditor	“dft” or “all contexts”	See “Tessent DesignEditor” on page 43.
Tessent Scan (formerly DFTAdvisor)	dft -scan	See the “Inserting Internal Scan and Test Circuitry” section in the *Tessent Scan and ATPG User’s Manual*.
Tessent Diagnosis	patterns -scan_diagnosis	See the *Tessent Diagnosis User’s Manual*.

Overview

This section summarizes the features and inputs/outputs of the products documented in this manual.

- "Tessent FastScan and Tessent TestKompress" on page 41
- "Tessent Scan" on page 44
- "Tessent DesignEditor" on page 43
- "Tessent Diagnosis" on page 45
- "Tessent IJTAG" on page 45

Tessent FastScan and Tessent TestKompress

Tessent FastScan and Tessent TestKompress share a great deal of functionality. Tessent TestKompress contains the entire Tessent FastScan feature set (the "patterns -scan" context), and in addition provides functionality for EDT IP creation (the "dft -edt" context).

Both products share the following features:

- Can be used within a Mentor Graphics flow or as a point tool in other design flows.
- Contain an internal high-speed fault simulator.
- Produce a number of standard test pattern data formats.
- Contain a powerful design rules checker.
- Read most standard gate-level netlists.
- Produce very high coverage test pattern sets for full-scan and scan-sequential designs. Scan-sequential designs contain well-behaved sequential scan circuitry, including non-scan latches, sequential memories, and limited sequential depth.
- Contain functionality for handling embedded RAM and ROM.
- Support the same pattern types and fault models.
- Provide the same test coverage.
- Provide the same diagnostics.
- Contain the same command set, with the exception that Tessent TestKompress contains additional commands for EDT IP creation and use.

In addition to the previous features, Tessent TestKompress includes the following:

- Increases production throughput: scan test time is much shorter than any other scan methodology.

Tessent FastScan and Tessent TestKompress Inputs

Tessent FastScan and Tessent TestKompress have the following inputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.
- **Test Procedure File** — This file defines the operation of the scan circuitry in your design. You can generate the file by hand or by using the write_atpg_setup command in Tessent Scan. For more information about test procedure files, refer to the "Test Procedure File" chapter of the *Tessent Shell User's Manual.*
- **Library** — This file contains model descriptions for all library cells used in your design.
- **Test Patterns** — This is a set of externally generated test patterns that you can use as the pattern source for simulation.

Tessent TestKompress has the following inputs:

- EDT IP Creation Phase:
  - **Design** — This must be a gate-level netlist with scan. The supported netlist format is Verilog.
  - **Test Procedure File** — This file defines the operation of the scan circuitry in your design. You can generate the file by hand or by using the write_atpg_setup command in Tessent Scan. For more information on test procedure files, refer to the "Test Procedure File" chapter of the *Tessent Shell User's Manual*.
  - **Library** — This file contains model descriptions for all library cells used in your design.
- EDT Pattern Generation Phase:
  - **Design** — This must be a scan-inserted, gate-level netlist with EDT circuitry. The supported netlist format is Verilog.
  - **EDT Dofile** — Created by Tessent TestKompress in the IP Creation Phase, this file contains setup commands for the Pattern Generation Phase.
  - **EDT Test procedure file** — Created by Tessent TestKompress in the IP Creation Phase, this file contains test procedure steps for the Pattern Generation Phase.
  - **Library** — This file contains model descriptions for all library cells used in your design.

Tessent FastScan and Tessent TestKompress Outputs

Tessent FastScan and Tessent TestKompress produce the following outputs:

- **Test Patterns** — This file set contains test patterns in one or more of the supported simulator or ASIC vendor pattern formats. For more information on the available test

pattern formats, refer to the write_patterns command reference page within this manual, or the "Saving the Test Patterns" section in the *Tessent Scan and ATPG User's Manual*.

- **ATPG Information Files** — These files contain session information that you can save using various commands.
- **Fault List** — This is an ASCII file that contains internal fault information in the standard Mentor Graphics fault format.

Tessent TestKompress produces the following outputs:

- EDT IP Creation Phase:
  - **EDT IP Files** — These files contain the EDT IP described in Verilog or VHDL RTL, as well as connectivity and a black box representation of the core design.
  - **Design Compiler Synthesis Script** — This is a synthesis script, typically used as a template for synthesizing the EDT IP into the design.
  - **EDT Dofile** — This file contains setup commands for the EDT Pattern Generation Phase.
  - **EDT Test Procedure File** — This file contains test procedure steps for the Pattern Generation Phase.
  - **Bypass Files** — These files consist of a dofile and a test procedure file for optionally performing Tessent FastScan ATPG on the design with EDT.
- EDT Pattern Generation Phase:
  - **Test Patterns** — This file set contains test patterns in one or more of the supported simulator or ASIC vendor pattern formats. For more information on the available test pattern formats, refer to the write_patterns command description in this manual.

Tessent DesignEditor

Tessent DesignEditor features contain a subset of Tessent Shell features.

Tessent DesignEditor features include the following:

- Access to design introspection and editing features while consuming a less expensive product license.
- Access to the commands that can operate in the dft context (commands labeled "dft" or "all contexts").

Tessent DesignEditor Inputs

Tessent DesignEditor has the following inputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.

- **Library** — This file contains model descriptions for all library cells used in your design.

Tessent DesignEditor Outputs

Tessent DesignEditor produces the following outputs:

- **Design** — The supported netlist formats are: gate-level Verilog, RTL Verilog, RTL System Verilog, and RTL VHDL.

Tessent Scan

Tessent Scan-specific features include features that support scan insertion.

Specifically, Tessent Scan supports the following functionality:

- Support for full-scan identification and insertion.
- Support for common scan methodologies including Mux-scan, Clocked-scan, and LSSD.
- Powerful design rules checking.
- Automatic generation of the scan setup dofile and the test procedure files for use downstream in your flow with Tessent FastScan and Tessent TestKompress ATPG products.
- Display of a variety of information—from design and debugging information to statistical reports for the test set you generate.

Tessent Scan Inputs

Tessent Scan has the following inputs:

- Design Netlist — In Verilog format.
- Test Procedure File — Required if you have existing scan circuity in your design. The test procedure file defines the operation of existing scan circuitry. See also "Specifying Existing Scan Information."
- DFT Library — Contains the model descriptions for all library cells used in your design, along with the model descriptions for all the scan replacement cells.
- **Command Dofile** — A text file containing a list of Tessent Scan commands. You can also enter these commands interactively.

Tessent Scan Outputs

Tessent Scan produces the following outputs:

- Design Netlist — A scan version of your design netlist that can be in Verilog format.

- ATPG Setup Files — The test procedure file, which defines the operation of the scan circuitry in your design, and a dofile for setting up the design and scan circuitry information for ATPG operations.

Tessent Diagnosis

Tessent Diagnosis-specific features include the following:

- Fault model independent analysis for suspect identification, suspect scoring, and classification.
- Logic and chain diagnosis.
- Direct diagnosis with compressed patterns.
- Links to Calibre® for physical view.

Tessent Diagnosis Inputs

Tessent Diagnosis has the following inputs:

- **Design** — This must be a flattened design, created previously using the write_flat_model command in Tessent FastScan or Tessent TestKompress.
- **Test Patterns** — STIL, WGL, binary or ASCII version of the patterns applied on the tester.
- **Failure file** — This file contains ATE failure data presented in the correct Mentor Graphics failure file format for the diagnose_failures command.

Tessent Diagnosis Outputs

Tessent Diagnosis produces the following outputs:

- **Failure Diagnosis Report** — This is a human-readable diagnosis report that is displayed onscreen or written in ASCII format to a file. Additionally, the report can be written to a file in Comma Separated Value (CSV) format.

Tessent IJTAG

Tessent IJTAG is Mentor Graphics implementation of the IEEE P1687 (IJTAG) for PDL command retargeting and ICL extraction. For complete information, refer to the *Tessent IJTAG User's Manual*.

Tessent IJTAG Inputs

Tessent IJTAG produces the following input:

- **ICL Files** — Instrument Connectivity Language (ICL) descriptions of your design.

Tessent IJTAG Outputs

Tessent IJTAG produces the following outputs:

- **Test Patterns** — Retargeted PDL patterns in many different ATE tester specific formats and Verilog HDL simulation test benches.
- **Extracted ICL Files** — Top-level ICL expressing the interconnection of IJTAG instruments within a design netlist.

Optimization of Adobe Reader

You can optimize your ability to navigate through the manuals by customizing your Adobe Reader user settings to display the and icons. These Previous View and Next View icons allow you to retrace your viewing history. This optimization is particularly useful for navigating the configuration data syntax presented in the Configuration-Based Specification chapter of this manual.

You can enable these icons by clicking the right mouse button on the tool banner and selecting **Page Navigation > Previous View | Next View** from the popup menu. After you enable these icons, they will be persistent in your personal Adobe Reader environment.

Chapter 2
Shell Commands

The shell commands described in this chapter invoke tools that create, edit, manipulate, or diagnose test patterns for DFT applications. These commands are issued from the input window of your Linux workstation and by default, open in a command line session.

Shell Command Descriptions

The notational conventions used to describe the shell commands are the same as those used in other parts of the manual. Do not enter any of the special notational characters (such as, {}, [], or |) when typing the command. For a complete description of the notational conventions used in this manual, refer to "Command Line Syntax Conventions" on page 341.

Table 2-1 contains a summary of the shell commands described in this chapter.

Table 2-1. Shell Command Summary

Command	Description
create_skeleton_design	Generates files needed to create Tessent TestKompress logic at the RTL stage.
stil2mgc	Invokes stil2mgc to convert dofiles and test procedure files for DFT applications.
tessent	Invokes a Tessent tool in a command-line session.

create_skeleton_design

Usage

create_skeleton_design -i *skeleton_design_input_file*
[-o *output_file_prefix*]
[-simulation_library]
[-design_interface *file_name*]
[-module_name *module_name*]
[-help [-verbose]]

Description

Invokes Tessent TestKompress and creates files necessary to integrate Tessent TestKompress logic (TestKompress logic) into a design at the RTL stage.

This tool requires a special design skeleton input file that you create manually. For more information about this file, see "Integrating Compression at the RTL Stage" in the *Tessent TestKompress User's Manual.*

Arguments

- -i *skeleton_design_input_file*

  A required switch and string pair that specifies the pathname of the skeleton design input file.

- -o *output_file_prefix*

  An optional switch and string pair that specifies a naming prefix for the output files as follows:

  <*output_file_prefix*>.v
  <*output_file_prefix*>.dofile
  <*output_file_prefix*>.testproc
  <*output_file_prefix*>.atpglib

  By default, *test* is used for the naming prefix.

- -simulation_library

  An optional switch that creates a Verilog simulation library from the specified ATPG library.

- -design_interface *file_name*

  An optional switch and string pair that specifies the pathname of the file containing a Verilog description of the design interface. The Verilog description file is used when the TestKompress logic is placed externally to the design core.

- -module_name *module_name*

  An optional switch and string pair that specifies the name of the generated skeleton design module. When this switch is not specified, the default module name is "skeleton_design_top".

This switch is useful when a design created using the skeleton flow contains multiple EDT blocks. Normally, this would result in all of the EDT blocks having the same name (i.e. skeleton_design_top_edt). You can use this switch during the skeleton design generation step to provide different names for different EDT blocks.

- -help

  An optional switch that lists all the invocation switches.

- -verbose

  An optional switch that, together with -help, lists all the invocation switches and a brief description of each.

stil2mgc

Scope: Converts STIL files to dofiles and test procedure files for Tessent FastScan, Tessent TestKompress, and Tessent Scan.

Usage

stil2mgc {-**STil** ***stil_filename*** [-**TPf** ***tpf_filename***] [-**DOfile** ***dofile_name***]
[-FLex_dofile *dofile_name*]
[-ALias Min | All] [-CApture NOne | Single | NAmed]
[-LOgfile *logfile_name* [-REplace]]} |
[-help | -Usage | -MANual | -Version] [-Verbose]

Description

Invokes stil2mgc and produces a dofile for Tessent FastScan, Tessent TestKompress, and Tessent Scan that defines clocks, scan chains, scan groups, and pin constraints. This tool also creates test procedure files with a timeplate and the following standard scan procedures: test_setup, load_unload, and shift.

The tool translates STIL signal groups, which are used in timeplates or procedures, into “alias” statements in the test procedure file. It also produces a test procedure file timeplate definition for each WaveformTable in the STIL file, exactly matching the timing specified in the STIL file.

Any procedure or macro with a name that matches a Mentor Graphics procedure type (load_unload, master_observe) is translated into that Mentor Graphics procedure. Any procedure or macro in the STIL file that has “capture” in its name is translated into a named capture procedure when you use the “-Capture Named” switch.

Any other macro whose name does not match anything that Mentor Graphics uses is translated into an unused sub-procedure.

For more information about translation details, refer to “Notes About Using the stil2mgc Tool” in the *Tessent Shell User’s Manual*.

Arguments

- **-STil** ***stil_filename***

  A required switch and string pair that specifies the name of the input STIL Procedure File (SPF).

- **-TPf** ***tpf_filename***

  An optional switch and string pair that specifies the name of the test procedure file to generate. If not specified, the *tpf_filename* will be named by appending “.proc” to the STIL Test Procedure file name.

- **-DOfile *dofile_name***

  An optional switch and string pair that specifies the name of the dofile to generate. If not specified, the *dofile_name* will be named by appending ".dof" to the STIL Test Procedure file name.

- -FLex_dofile *dofile_name*

  An optional switch and string pair that produces an additional dofile targeted at the FlexTest tool.

- -ALias Min | All

  An optional switch and literal pair that produces the minimum required alias statements in the MGC Procedure file or to produce alias statements for all signal groups found in the STIL Test Procedure file. The default is to produce the minimum required alias statements.

- -CApture NOne | Single | NAmed

  An optional switch and literal pair that adds information to the MGC Procedure file. This switch will either produce no capture procedures, a single default capture procedure, or multiple named capture procedures for each capture Macro found in the STIL Test Procedure File. The default is to produce no capture procedures.

- -LOgfile *logfile_name*

  An optional switch and string pair that specifies the name of the file to write all session information.

- -REplace

  An optional switch that overwrites the -Logfile *logfile_name* if one by the same name already exists.

- -help

  An optional switch that displays a message that contains all the **stil2mgc** switches and a brief description of each.

- -Usage

  An optional switch that displays the usage syntax for the **stil2mgc** command.

- -MANual

  An optional switch that opens the Tessent Documentation System.

- -Version

  An optional switch that displays the version of the **stil2mgc** tool that you currently have available.

Examples

The following example executes the **stil2mgc** tool on *design.spf*.

```
shell> stil2mgc -stil design.spf -tpf new_design.tpf
         -dofile new_dofile.do
```

tessent

Usage

tessent {-Shell
| {-DIAGSERVER *diagnosis_arguments*}
| {-YIELDINSIGHT [-NOGui]}
| {-Siliconinsight {-Desktop | -Ate}}
[-DOFile *dofile_name*... [-HIStory]]
[-Arguments {*name=value*}...]
[-LOGfile *logfile_name* [-REPlace]]
[-LICense_wait {*minutes* | NONE | UNLimited}]
[-underscore_commands_only]
| [-Help | -Usage | -Manual | -Version]

Description

Invokes a Tessent tool in a command-line session.

Arguments

Tessent Shell Arguments

- -Shell

  A required switch for invoking Tessent Shell. For more information, refer to the *Tessent Shell User's Manual*.

- -DOFile *dofile_name*... [-HIStory]

  An optional switch and repeatable string pair that specifies the name of one or more dofiles to execute upon invocation. As the tool is processing each dofile, the Tcl variable "tessent_user_argv0" is assigned the name of the current dofile. -HIStory is an optional switch that adds dofile commands to the command line history list. The tool ignores the -History switch if you issue it without the -Dofile switch.

- -Arguments {*name=value*}...

  An optional switch and repeatable name/value pair that specifies variable names and values in a list named "tessent_user_arg." No spaces are allowed between the name, the equal sign, and the value. This list can later be accessed by a dofile for the purpose of controlling parameters in the dofile. For more information, refer to "Example 2" on page 55.

Tessent Diagnosis Server Arguments

-DIAGSERVER {[-DAEmon [*daemon_id*]] -DOFile *dofile_name*} [-HDB *history_database_name*]
| [{-DSTATUS | -DEXIT | -DTERMINATE} *daemon_id* | [-DLIST]]

- -DIAGSERVER

  A required switch for invoking Tessent Diagnosis server. See "Running Tessent Diagnosis Server" in the *Tessent Diagnosis User's Manual*.

- -DOFile *dofile_name*... [-HIStory]

  An optional switch and repeatable string pair that specifies the name of one or more dofiles to execute upon invocation. -HIStory is an optional switch that adds dofile commands to the command line history list. The tool ignores the -History switch if you issue it without the -Dofile switch.

- -DAEmon *daemon_id*

  An optional switch that specifies invoking the Tessent Diagnosis server in daemon mode. The tool automatically assigns a process ID. Using the optional *daemon_id*, you can specify a process ID for the daemon.

- -HDB *history_database_name*

  An optional switch and string pair that creates a server history SQL database. If the named database already exists, then Tessent Diagnosis server appends the database during subsequent diagnosis runs.

- -DSTatus *daemon_id*

  An optional switch and integer pair that queries the status of a daemon you identify with *daemon_id* and displays the status of the monitors and analyzers.

- -DEXit *daemon_id*

  An optional switch and integer pair that instructs the daemon to exit after the tool finishes any running diagnosis jobs.

- -DTErminate *daemon_id*

  An optional switch and integer pair that instructs the daemon to immediately exit without finishing any running diagnosis jobs.

- -DLIst

  An optional switch that lists running daemons, including the id, host, and logfile for each daemon.

Tessent YieldInsight Arguments

-YIELDINSIGHT [-NOGui]

- -YIELDINSIGHT

  A required switch for invoking Tessent YieldInsight. See the *Tessent YieldInsight User's Manual* for complete information.

- -NOGui

  An optional switch that invokes the tool in command line mode. By default, Tessent YieldInsight invokes in graphical user interface (GUI) mode.

- -DOFile *dofile_name*... [-HIStory]

  An optional switch and repeatable string pair that specifies the name of one or more dofiles to execute upon invocation. -HIStory is an optional switch that adds dofile commands to the

command line history list. The tool ignores the -History switch if you issue it without the -Dofile switch.

Tessent SiliconInsight Arguments

-Siliconinsight {-Desktop | -Ate}

- -Siliconinsight

  A required switch for invoking Tessent SiliconInsight.

- -Desktop | -Ate

  A required literal choice that specifies which Tessent SiliconInsight tool to invoke.

  Choose one of the following options:

  -Desktop — Invoke Tessent SiliconInsight Desktop.

  -Ate — Invoke Tessent SiliconInsight ATE.

- -DOFile *dofile_name*

  An optional switch and string pair that specifies the name of a dofile to execute upon invocation.

For information about these switches, refer to the *Tessent SiliconInsight User's Manual for Tessent Shell*.

Common Arguments Regardless of Mode

- -LOGfile *logfile_name*

  An optional switch and string pair that specifies the name of the file to which you want Tessent Diagnosis to write all session information. The default is to display session information to the standard output. The version banner that indicates the tool, version, date, and platform on which the log file was produced is included at the beginning of the file.

- -REPlace

  An optional switch that overwrites the -Logfile *logfile_name* if a log file of the same name already exists.

- -LICense_wait *minutes* | NONE | UNLimited

  An optional switch and integer, or switch and literal, that specifies the tool's response if the license is unavailable.

  Choose one of the following options:

  minutes — A positive integer that specifies the number of minutes to wait for the license.

  NONE — A literal that directs the Tessent tool to exit immediately if no license is available.

  UNLimited — A literal that directs the Tessent tool to wait with no time limit for a license. This is the default.

- -underscore_commands_only

  An optional switch that directs the tool to only allow commands that use the underscore style. This option disables the legacy commands that used spaces. For example, if this option is specified, the tool would accept analyze_drc_violation but would not accept “analyze drc violation”.

- -Help | -Usage

  An optional switch that lists the switches for the tessent command.

- -Manual

  An optional switch that opens the Tessent Documentation System.

- -Version

  An optional switch that displays the version of the tessent tool you specify.

Example 1

The following example invokes Tessent Shell, uses the logfile *myLogfile* replacing any existing logfile with the same name, and executes the dofile *myDofile*.

tessent -shell -logfile myLogfile -replace -dofile myDofile

Example 2

The following example invokes Tessent Shell and runs a dofile named dofile2. The command line also specifies two variable/value pairs that are placed in a Tcl list named “tessent_value_arg” and thus made available to the dofile.

% **tessent -shell -dofile dofile2 -arguments depth=2 output_dir=outDir**

The following is the listing of dofile2, which demonstrates how to use the -arguments switch to set the values of variables inside the dofile. This technique allows you to reuse dofiles without modification.

```
# dofile2
# Set the default values of the control parameters
array set params {
   depth 0
   max_nodes -1
   output_dir ""
}

array set params $tessent_user_arg

# Use some params
if { $params(depth) > 0} {
  # do whatever needs to be done in this case…
}

if {  ! [file isdirectory $params(output_dir)] } {
  file mkdir $params(output_dir)
}
```

Example 3

The following example shows how to create a single shell script that invokes and passes arguments to Tessent Shell, which then executes the commands in the shell script as a regular dofile. In order for the following to work, the shell script file must have executable permissions.

The contents of the shell script, called tScript in this example, are as follows.

```
#!/bin/sh
#\
exec tessent -shell -dofile "$0" -arguments ${1+"$@"}

set_transcript_style off
puts "$tessent_user_arg"

# add dofile commands here

exit
```

The Linux shell interprets the second line ('#\') as a comment and then executes the third line, which invokes Tessent Shell and passes the entire shell script as a dofile. (Tessent Shell's Tcl interpreter ignores the second and third lines of the shell script and then interprets all following lines as normal Tessent Shell commands.)

The -arguments switch on the third line allows you to pass an arbitrary number of argument/value pairs from the shell script invocation into a standard Tcl list called "tessent_user_arg" for later parsing and use by Tessent Shell. So, for example, when you invoke the shell script as follows:

```
% tScript myarg1=myvalue1 myarg2=  myarg3=myvalue3
```

the three arguments and their values are passed to Tessent Shell, and the relevant part of the transcript would appear as follows:

```
//  command: #!/bin/sh
//  command: # exec tessent -shell -dofile "$0" -arg ${1+"$@"}
//  command: set_transcript_style off
myarg1 myvalue1 myarg2 {} myarg3 myvalue3
```

Chapter 3
Data Models

Introduction

Tessent Shell has an internal database that is organized into data models which are broad categories of design information (such as hierarchical design data). Each of the data models contains one or more types of design objects (such as pins and modules), and each design object has a list of attributes (such as an ID or bit-width of a bus).

For additional information about the design data models and how to work with them, refer to "Design Data Model, Attributes, and Introspection" in the *Tessent Shell User's Manual*.

You can access the pre-defined attributes on those design objects using the *_attribute* tool commands listed in Table 4-1 on page 103. Those commands also provide a way for you to register new user-defined attributes for those design objects in the database.

The following sections describe the various data models, the types of objects they can contain, and the attributes associated to the objects:

- "Hierarchical Design Data Model" on page 58
- "Flat Design Data Model" on page 80
- "ICL Data Model" on page 87

Hierarchical Design Data Model

The hierarchical design data model contains five different object types: module, instance, port, pin, and net. As suggested by Figure 3-1, instances, pins, and nets are hierarchical objects that exist relative to the current design. Ports and modules are non-hierarchical objects.

The *current design* is the design specified by the set_current_design command.

Figure 3-1. Tessent Shell Design Object Model

Hierarchical Object Types

The six hierarchical design object types are described on the following reference pages: Module, Instance, Port, Pin, Net, and Pseudo_port.

Reference information about attributes is provided in section "Attributes" on page 103.

Module

Description

A module has a simple non-hierarchical name. A module definition can come from a Verilog module, a VHDL entity, a Tessent library model, or it can be a built-in primitive.

The module object type interacts with attributes as follows:

- Attributes are automatically visible as read-only attributes on instances if the same attribute is not also registered on the instance object type. Such attributes remain stored on the module definition and not on the instance itself
- Attributes with the applies_to_child_instances option set to On are visible to all child instances below the module.

Built-In Attributes

The module object type has the following attributes:

cell_type	String that reports characteristics of the cell. This attribute is initially null and is populated by the set_current_design command with information extracted from the cell library files. For example, any cell described as a pad in the library will have cell_type set to “pad”. If your cell library includes the scan mapping information, the non-scan flip-flop will be identified with a nonscan_dff type and the scan equivalent flip-flops will have mux_scan_dff type. See the read_cell_library command description for information on how the cell_type information can be loaded. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command if your cell library file only includes the ATPG cell modeling information. *Tessent Cell Library Manual*
file_path_name	String that specifies the pathname to the file where a given module is defined. This attribute is null for created modules or modules without a definition.
has_no_definition	Boolean that is true when a module does not have a definition, but a blackbox model was created during elaboration from its instantiation. You cannot have this type of module before creating the flat module unless you identify the module as a blackbox using the add_black_boxes command.
ijtag_is_icl_module	Boolean that identifies a design module as an ICL module. This attribute is only set in the patterns -ijtag context.
instrument_name	String that is set to the ICL module name it matches when its ijtag_is_icl_module attribute is true. The default is null.

is_created	Boolean that specifies whether the module was created using the create_module command.
is_hard_module	Boolean that specifies the module cannot be edited when set to true. This attribute is automatically set to true for all modules with type = “cell” or “primitive”. This attribute is set for design modules in the dofile using the following command: set_attribute_value -name is_hard_module. This property has applies_to_child_instances set to On by default.
is_incomplete	Boolean that specifies that the module cannot be edited and/or written out when set to true. This attribute is set to true when the module was read with the read_verilog or read_vhdl -blackbox commands, or when the module includes RTL constructs that are not supported by the set_context -no_rtl option. The is_hard_module attribute automatically returns true for any module with the is_incomplete attribute set to true. To write out a module with only its port and parameter definition, read it in normally and write it back out using the write_design -interface option.
is_modified	Boolean that specifies that a module read in from a file was edited during the insertion mode. This attribute is set as soon as the module is modified and remains set until the insertion state is left. See the get_modules command description for usage examples.
is_physical_module	Boolean that specifies that the module is a physical block. It gets set during design elaboration if the module is found in an open TSDB and its level was defined as chip or physical_block when its TSDB was created.
is_power_always_on_cell	Boolean that is set to true when the module is specified as an always_on cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_isolation_cell	Boolean that is set to true when the module is specified as an isolation cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_level_shifter_cell	Boolean that is set to true when the module is specified as a level shifter cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_retention_cell	Boolean that is set to true when the module is specified as a retention cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.

is_unsaved	Boolean that specifies that a module that was either modified or created within the insertion mode of the dft context was not yet written out. This attribute is set as soon as the module is modified or created and is reset as soon as the module is saved using the write_design command. See the get_modules command description for examples of its usage.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
language	String that specifies the supported library language. Set to “tessent_lib” for Tessent library models. Set to “verilog” for Verilog modules and Verilog primitives. Set to “vhdl” for VHDL entities.
library_name	String that specifies the logic name of the library containing the module definition. All commands that accept a module name look for the module in the default library as specified by the set_logical_design_libraries command. You can use the get_modules command to access modules from different libraries. Libraries are only supported in -rtl sub-contexts. In -no_rtl contexts, one library exists and it is named “work”.
line_number	Integer that specifies a line number in the file where a given module is defined. This number is 0 for created modules and for modules without a definition.
master_name	String that specifies the real name of the module as it was defined independently of the parameterized view.
name	String that specifies the name of the module. Modules are defined from the following sources: • read_verilog files • read_vhdl files • create_design and copy_design commands • read_cell_library files • primitives have built-in names For parameterized modules, a unique name is created for each parameterized view by appending to the master_name the string @PV# where # is an integer starting from 1 and incremented for each parameterized view. Use the get_module_parameter_list and get_module_parameter_value commands to introspect the parameter values.
object_type	Returns the object data type “module”.
power_domain_name	Returns the name of the power domain associated to the current design. This attribute is null for all other modules. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.

preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins on all instances of the module will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the module. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
synthesize_before_analysis	Boolean that specifies that the given module is to be synthesized when going to analysis mode. During ICL extraction, the combinational path between the IJTAG port of the modules having a corresponding ICL module is traced and any module encountered along the way is synthesized. If you use a test_setup procedure during ICL extraction, you must set this attribute on all RTL modules which must be synthesized in order for the test setup simulation to propagate its value to the entire ICL network as the pretracer does not traverse sequential cells. The quick synthesis engine uses a cell library defined in the build tree at the given location "$TESSENT_HOME/lnx-x86/lib64/hdleng/lib". Both Tessent and Verilog cell library models are supplied, namely "dft_sim.atpg" and "dft_sim.v". The tessent libraries are automatically loaded when synthesis is used.
type	Set to "cell" for the following modules: • Models read in with read_cell_library. • Verilog modules surrounded by the `celldefine/`endcelldefine directives and read in with read_verilog. Set to "primitive" for the following modules: • Verilog primitives used in the design. Set to "design" for all other modules.
vhdl_architecture	String that reports the architecture of vhdl modules. It is null for modules of other languages. All commands that accept a module name return the vhdl entity associated with the default architecture which is the last compiled version. Use get_modules to access modules with the non default architecture.

Inheritance

Built-in inherited attributes:

- None

Related Commands

get_attribute_list	get_name_list
get_attribute_value_list	get_pins
get_common_parent_instance	get_ports
get_modules	report_attributes

Module Specification

A module object (module_object) is specified by a module name which is a string. For example: “modA”.

Instance

Description

An instance is a single instantiation of a module. No instance object exists until the set_current_design command is executed.

The instance object type interacts with attributes as follows:

- Module attributes are automatically visible as read-only attributes on corresponding instances if the instance object type does not have the same attribute registered.
- Attributes defined with the applies_to_child_instances option set to On automatically become visible to all child instances of the instance object.

Built-In Attributes

ignore_during_icl _extraction	When set to true, even if the instance has an associated ICL module during ICL extraction, the instance is ignored and not reported in the extracted ICL. This attribute is useful to allow extracting the ICL for the portion of the network that is correct while other instances still have issues to resolve. The generated ICL module will have the tessent_ignored_design_instances attribute defined referencing all design instances that were ignored.
in_graybox	Set to true when the instance is included in the graybox netlist. Set to false when the instance is excluded from the graybox netlist, which is the default for all the instances in the design. You can change the attribute value with the analyze_graybox or set_attribute_value command. For more information about this attribute, refer to the analyze_graybox command description.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_block_id	The leaf_name of instances located inside generate blocks have the generate block ids joined by periods prepended to their instantiation name. This attribute returns the block_id part of the leaf_name. It is null for instances that are not inside generate blocks.
leaf_name	String that specifies the name of the instance (value of the name attribute) without the hierarchical path.

leaf_name_hash	This attribute is normally identical to the leaf_name attribute except when the leaf instance is located inside a generate loop construct inside an RTL file. The leaf_name includes the block id with the loop index such as in loopA[4].u2. The leaf_name_hash attribute is the same except that the loop index is replaced by a hash sign as shown here: loopA[#].u2. You use this attribute if you are editing the content of generate loops and you have not enabled auto uniquification. For the delete_connections and move_connections commands, you must use a look up table with <parent_module>.<leaf_nane_hash>.<pin_leaf_name> entries to know if you have already processed that pin. See the examples in the move_connections and get_dft_cell command descriptions for examples of such usage.
master_module_name	String that specifies the value of the master_name on the module object associated with the instance.
module_name	String that specifies the value of the name of the module object associated with the instance.
name	String that specifies the hierarchical name of the instance relative to the current design. The name of every instance is unique.
object_type	Returns the object data type “instance”.
parent_instance	String that specifies the instance name in which the instance exists. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the /<leaf_name> part of the path.
power_domain_name	Returns the name of the power domain associated to the instance. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins on the instance will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the instance. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.

Inheritance

Built-in attribute inheritance from associated module objects:

- cell_type
- has_no_definition
- ijtag_is_icl_module
- is_created

- is_hard_module
- is_incomplete
- is_modified
- is_power_always_on_cell
- is_power_isolation_cell
- is_power_level_shifter_cell
- is_power_retention_cell
- is_unsaved
- language
- library_name
- preserve_boundary
- type
- vhdl_architecture

Related Commands

get_attribute_list	get_name_list
get_attribute_value_list	report_attributes
get_common_parent_instance	

Instance Specification

An instance object (instance_object) is specified by a complete hierarchical instance pathname. For example: “/u1/u2/u3”.

Port

Description

Ports have a simple non-hierarchical name. A port is an object on a module and can have an input, output or inout direction.

One port object exists for each bit of a bused port so every bit of a bussed port can be attributed independently.

The port object type interacts with attributes as follows:

- Attributes defined on ports are automatically visible as read-only attributes on the associated pin objects unless the attribute is also registered for the pin object type. This is the case for the name attribute which is defined for both port and pin object types. These attributes are stored on the associated port of the pins and not on the pin object itself.

Built-In Attributes

bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.
bus_name	String that specifies the name of the bus without the index. <name> = bus_name [index] when is_bus is true; otherwise, bus_name is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction. This attribute follows the to and downto BIT_VECTOR types in VHDL.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether left_index is smaller, larger than, or equal to right_index.
constraint_value_ during_load_unload	String that specifies a constant value for a top-level port during load_unload test procedure retargeting. Possible values are: 0, 1, X, or Z. Constraining the value of the top-level port enables tracing of signals from the core level to the chip level.
direction	String that specifies the direction of the port. Possible values are: input, output, or inout.

function	String that either reports the function of the port on cell modules or reports the presence of the power or ground attributes on ports of the current_design. For cell modules, this attribute is initially null and is set by the set_current_design command from information extracted from the cell library files. For information about how cell_type information can be loaded, refer to the read_cell_library command. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command in case your cell library file only includes the ATPG cell modeling information. See *Tessent Cell Library Manual* for a list of available function values. For a top-level module, this attribute is initially null and you can set one of the following values on an input/inout port with the set_attribute_value command: • **power** — Constrains power input/inout ports during circuit setup and DRC. • **ground** — Constrains ground input/inout ports during circuit setup and DRC. For more information about using these values, refer to "Excluding Power and Ground Ports from the Pattern Set" in the *Tessent Scan and ATPG User's Manual*.
gate_pin_id	Returns the id of a gate_pin when the pin has an associated gate_pin inside the flat model. Exists for cell pins associated to fault sites and for hierarchical pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.
has_functional_source	Returns true unless the port is of direction output and the port net is undriven or tied.
ignore_for_graybox	Set to true when an output port is to be excluded from graybox analysis. By default, this attribute is set to false for all output ports (considered by the graybox analysis backtracing). Setting this attribute on an input port has no effect on the analyze_graybox command. You need to exclude the scan_out ports of the core chains (or channel outputs if it's a design containing EDT hardware) from graybox analysis using this attribute because the tool has no way of knowing which outputs are core chain scan output ports. For more information about this attribute, refer to the analyze_graybox command description.
ijtag_c0	Boolean attribute that is set on the design ports of a module that has a corresponding ICL module, if the port name is listed in the forced_low_output_port_list attribute on the ICL module.

ijtag_c1	Boolean attribute that is set on the design ports of a module that has a corresponding ICL module, if the port name is listed in the forced_high_output_port_list attribute on the ICL module.
ijtag_connection_rule_ option	An attribute that reflects the connection_rule_option attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_forced_high_ output_port_list	An attribute that reflects the force_high_output_port_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_forced_low_ output_port_list	An attribute that reflects the force_low_output_port_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_function	String that reflects the port function of the ports as described in the ICL module. Its value, which is populated in the ICL extraction mode of the patterns -ijtag context, is the port function with an underscore separating the words. For example, a ScanInPort in ICL has icl_function equal to scan_in.
ijtag_function_modifier	An attribute that reflects the function_modifier attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_logical_hier_ connection_from_src	An attribute that is set on output ports and contains the port on the module that is the logical source of the output port. It is extracted from the associated ICL module attribute ijtag_logical_source = “{port1 port2} {port3 port4} ...”
ijtag_logical_hier_ connection_to_dst	This attribute is set on input ports and contains the ports on the module that are the logical destinations of the input port. It is extracted from the associated ICL module attribute ijtag_logical_source = “{port1 port2} {port3 port4} ...”
index	Integer that specifies the index of the port that is already part of the name when the port is part of a bus.
is_bus	Boolean that specifies whether the port is part of a bus. This attribute is set to true when the port is part of a bus.
is_excluded_from_ isolation_constraints	Specifies that during retargetable pattern generation, the input ports with this attribute should not be constrained to X. This attribute is only used during core-level pattern generation (“set_current_mode -type internal” and patterns -scan context).
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
library_name	String that specifies the library the port belongs to.

master_module_name	String that specifies the value of the master_name on the module object the port belongs to.
module_name	String that specifies the name of the module object the port belongs to.
name	String that specifies the name of the port object. One port object exists for each bit of a bused port and the name includes the index of the port. For example: A[3]
object_type	Returns the object data type “port”.
power_domain_name	Returns the name of the power domain of the current design. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins of the port will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the module. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
special_drive	String value extracted from the cell library data. See the read_cell_library command for information on how cell_type information can be loaded. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command in case your cell library file only includes the ATPG cell modeling information. Possible values are: open_drain | open_source | pull0 | pull1.
tie_value	String that indicates the value to which the port is tied. Possible values are: 0, 1, X, Z, or “” (empty string). The default is the empty string which means the port is not tied to a value.

Inheritance

Built-in attribute inheritance from associated objects:

- None

Port Specification

A port object (port_object) is an input, output, or inout interface of a module, which is specified by a string. Examples of port names can be “In1”, “ClkA”, and “Out3”.

Pin

Description

A pin is an object on an instance that can be connected to other pins or ports with net objects. No pin object exists until the set_current_design command is executed.

The pin object type interacts with attributes as follows:

- Attributes defined on ports are automatically visible as read-only attributes on the associated pin objects unless the attribute is also registered for the pin object type. This is the case for the name attribute which is defined for both port and pin object types.
- Port attributes are stored on the associated port of the pin and not on the pin object itself.
- Attributes defined on a net are automatically visible by a pin having the exact same name unless the attribute is also defined on the pin object type. The reverse is also true. Attributes defined on a pin are automatically visible by a net having the exact same name unless the attribute is also defined on the net object type. This behavior enables you to register an attribute for net object types and have the attribute fully visible from the root-level ports and the hierarchical pins.

Built-In Attributes

base_name	String that specifies the name of the pin without the leaf name.
fault_site	String that is populated in the analysis mode of the patterns -scan context and reports if the pin is a fault site for 0, 1, or both fault polarity types. The attribute is null on pins that are not a fault site for both polarities.
gate_pin_id	Returns a gate_pin id when the pin has an associated gate_pin inside the flat model. Set to true for cell pins associated to fault sites and for hierarchical pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.
has_functional_source	Returns true unless the pin is of direction input and the pin is not connected, is connected to an undriven or tied net or is connected to a constant.
ijtag_logical_hier_ connection_from_src	Reflects the result of the add_ijtag_logical_source commands. Each destination points back to its logical source.
ijtag_logical_hier_ connection_to_dst	Reflects the result of the add_ijtag_logical_source commands. Each source points forward to its logical destinations.
is_hard_module	Boolean that reports the state of the is_hard_module attribute on the instance on which the pin exists.
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.

leaf_name	String that specifies the name of the pin (value of the name attribute) without the hierarchical path.
name	String that specifies the hierarchical name of the pin object relative to the current design. One pin object exists for each bit of a bused port; the name includes the index of the port appended to its associated instance name. For example: u1/u2/A[3].
object_type	Returns the object data type “pin”.
parent_instance	String that specifies the instance name of the instance on which the pin is instantiated. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the <leaf_instance_name>/<leaf_pin_name> part of the path. For example: parent_instance of pin (u2/u7/a) is u2 parent_instance of pin (u2/b) is null
parent_is_hard_module	Boolean that specifies whether the is_hard_module attribute on the pin’s parent instance is set to true. This attribute is set to true if the is_hard_module attribute on the pin’s parent instance is set to true. The default is false.
power_domain_name	Returns the name of the power domain of the instance to which this pin belongs. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, the hierarchical pin will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the instance. Any attribute stored on the hierarchical pin will be visible in the flat model. If you enable this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
tie_value	String that indicates the value to which the pin is tied. Possible values are: 0, 1, X, Z, or “” (empty string). The default is the empty string which means the pin is not tied to a value.

Inheritance

Built-in attribute inheritance from associated port objects:

- bus_left_index
- bus_name
- bus_range_direction
- bus_right_index
- bus_width
- direction

- function
- ijtag_function
- index
- is_bus
- library_name
- master_module_name
- module_name
- preserve_boundary
- special_drive

get_fanins	report_attributes
get_fanouts	

Pin Specification

A pin object (pin_object) is specified by a complete hierarchical pin pathname including the pin. For example: /u1/u2/u3/Y refers to pin Y of the hierarchical instance /u1/u2/u3.

Net

Description

No net objects exist until the set_current_design command is executed.

For every port and pin object, a net object with the same name exists. When objects are referenced by name in the editing and attribute commands, if a specified name exists as both a pin and a net or a port and a net, the pin or port is selected. If you want to force the selection of the net object that has the same name as a pin or port, use the get_nets introspection command. For examples of this usage, see the examples shown on the move_connections command reference page.

The net object type interacts with attributes as follows:

- Attributes defined on a net are automatically visible by a pin or port having the exact same name unless the attribute is also defined on the pin object type. The reverse is also true. Attributes defined on a pin or port are automatically visible by a net having the exact same name unless the attribute is also defined on the net object type. This is true for attributes on pins inherited from their associated port. This behavior enables you to register an attribute for the net object type and have the attribute fully visible from the hierarchical pins and from the ports of the current design.

Built-In Attributes

bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.
bus_name	String that specifies the name of the bus without the index. <name> = bus_name [index] when is_bus is true; otherwise, bus_name is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction. This attribute follows the to and downto BIT_VECTOR types in VHDL.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether left_index is smaller, larger than, or equal to right_index.
has_functional_source	Returns true unless the net is undriven or tied.
has_rtl	Boolean that indicates whether the net is connected to an RTL construct, such as an always block. Also indicates when the driver of the net is an RTL construct. The attribute is true under the following circumstances: • The net is used in an RTL expression. • The net is directly connected to a complex pin (not via an assign). The attribute is always false in the -no_rtl flow.

index	Integer that specifies the index of the net that is already part of the name when the net is part of a bus.
in_graybox	Set to true when the net is included in the graybox netlist. Set to false when the net is excluded from the graybox netlist, which is the default for all the nets in the design. The attribute value can be changed by the analyze_graybox or set_attribute_value command. For more information about this attribute, refer to the analyze_graybox command description.
is_bus	Boolean that specifies whether the net is a part of a bus. This attribute is set to true when the net is part of a bus.
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_block_id	The leaf_name of nets located inside generate blocks have the generate block ids joined by periods prepended to their local name. This attribute returns the block_id part of the leaf_name. It is null for nets that are not inside generate blocks.
leaf_name	String that specifies the name of the net (value of the name attribute) without the hierarchical path.
leaf_name_hash	This attribute is normally identical to the leaf_name attribute except when the leaf instance is located inside a generate loop construct inside an RTL file. The leaf_name includes the block id with the loop index such as in loopA[4].u2. The leaf_name_hash attribute is the same except that the loop index is replaced by a hash sign as shown here: loopA[#].u2. You use this attribute if you are editing the content of generate loops and you have not enabled auto uniquification. For the delete_connections and move_connections commands, you must use a lookup table with <parent_module>.<leaf_nane_hash>.<pin_leaf_name> entries to know if you have already processed that pin. See the examples in the move_connections and get_dft_cell command descriptions for examples of such usage.
library_name	String that specifies the library of the module in which the leaf net resides.
master_module_name	String that specifies the value of the master_name in which the leaf net resides.
module_name	String that specifies the name of the module object in which the leaf net resides.
name	String that specifies the hierarchical name of the net object relative to current design. One net object exists for each bit of a bused net; the name includes the index of the net appended to its associated instance name. For example: u1/u2/A[3].

object_type	Returns the object data type “net”.
parent_instance	String that specifies the instance name in which the net exists. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the /<leaf_name> part of the path.
parent_is_hard_module	Boolean that specifies whether the module containing the net has the is_hard_module attribute set to true. This attribute is set to true if the module containing the net has the is_hard_module attribute set to true. The default is false.
power_domain_name	Returns the name of the power domain of the instance in which this net exists. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.
tie_value	String that indicates the value to which the net is tied. Possible values are: 0, 1, X, Z, or “” (empty string). The default is the empty string which means the net is not tied to a value.

Inheritance

Built-in attribute inheritance from associated pin objects:

- Attributes defined on pins or ports having the same name as the net, if the attribute is not also registered on the net object type.

Net Specification

A net object (net_object), sometimes called just a net, is a wire that connects the pins of instances in the design. A net is specified by a hierarchical net pathname. In the following example, u5/u2/Q is a pin that drives the net u5/u2_Q. This example is based on the example design presented in the “Hierarchical Design Data Model” section of the *Tessent Shell User’s Manual*.

SETUP> get_fanouts u5/u2/Q

```
{u5/u1/A0 u5/u3/A0}
```

SETUP> get_fanouts u5/u2/Q -stop_on net

```
{u5/u2_Q}
```

Pseudo_port

Description

A pseudo_port represents a user-added primary input or primary output. A pseudo_port object enables the introspection of user-added primary inputs and outputs such as those created using the commands “add_primary_inputs”, “add_primary_outputs”, “add_primary_inputs -internal”, “add_primary_outputs -internal”, and “add_clocks -internal”.

A pseudo_port is not a real port in that it is not present in the original design, it cannot be used for design editing, and it is not reflected in designs written out using the write_design command. However, the pseudo_port is reflected in the flat model and it is used for analysis operations that use the flat model such as ATPG and simulation.

A pseudo_port shares some of the same attributes as the port object. Pseudo ports have a simple non-hierarchical name which may be the same as the pin's hierarchical name (for non-grouped pseudo_ports).

Pseudo_ports can be introspected with the get_ports command. The “real” pins that underlie a pseudo_port can be introspected with the “get_pins -of_pseudo_ports *pseudo_port_objects*” command.

The pseudo_port object type does not support attribute inheritance to the real underlying objects (pins/nets) associated to it. That is, the real design object behind the pseudo_port does not see the attributes set on this type of port.

Built-In Attributes

constraint_value_ during_load_unload	String that specifies a constant value for a top-level pseudo_port during load_unload test procedure retargeting. Possible values are: 0, 1, X, and Z. Constraining the value of the top-level pseudo_port enables tracing of signals from the core level to the chip level.
direction	String that specifies the direction of the pseudo_port. Possible values are: input and output.
gate_pin_id	Returns the id of the gate_pin associated with the pseudo_port inside the flat model.
is_bus	Boolean that specifies whether the pseudo_port is part of a bus. This attribute is always set to false. The pseudo_port object type does not support busses.
is_valid	Boolean that specifies whether the object still exists.
name	String that specifies the name of the pseudo_port object.
object_type	Returns the object data type “pseudo_port”.

Inheritance

Built-in attribute inheritance from associated objects:

- None

Flat Design Data Model

The flat design data model is an internal, flattened representation of the hierarchical design that is produced when exiting setup mode. You can also explicitly create the flat model using the create_flat_model command.

The flat design data model consists of gates that are connected together. A gate is an instance of a primitive module, and a gate_pin object represents a pin on a gate instance. Gates and gate_pins have no unique instance name, instead having a unique ID that is available to differentiate one from another. The format of the ID is two integers separated by a period character. The first integer represents the gate and the second integer represents the gate_pin. However, this ID does not remain in place from one netlist version to the next or from one Tessent Shell invocation to the next. For that reason, you should avoid hardcoding a gate ID into a script.

Flat Design Object Types

The gate_pin is the only object type in the flat model.

Gate_pin

Description

A gate_pin represents a pin on a gate instance in a flattened design.

Built-In Attributes

The gate_pin object type has the following attributes:

base_name	String that specifies the name of the instance in which the primitive module of the gate_pin is instantiated.
direction	String that specifies the direction of the gate_pin object: input (default) or output.
fault_site	String that is populated in the analysis mode of the patterns -scan context and reports if the pin is a fault site for 0, 1, or both fault polarity types. The attribute is null on pins that are not a fault site for both polarities.
gate_id	Integer that specifies the unique ID of the gate to which the gate_pin belongs. This integer is identical to the first integer in the gate_pin's id attribute. This value is not persistent and changes every time you create a flattened model.
hier_pin_name	String that specifies a hierarchical pin name when the gate_pin is associated to a hierarchical pin. This attribute is null when the gate pin is not associated to a hierarchical pin. Pins on hierarchical instances of type cells and pins on design modules that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true are the only hierarchical pins with a corresponding gate_pin.
id	Specifies a unique ID for each gate_pin that consists of two integers separated by a period: *gate_id.pin_index*
is_valid	Boolean that specifies whether the gate_pin object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the hierarchical pin name without the hierarchical path when the gate_pin is associated to a hierarchical pin. This is null by default.
name	String that specifies name of the gate_pin object. The value is the same as the hier_pin_name attribute when not empty; otherwise, the value is the same as the id attribute of the gate_pin object. Pins on hierarchical instances of type cells and pins on design modules that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true are the only hierarchical pins with a corresponding gate_pin.

object_type	Returns the object data type “gate_pin”.
parent_instance	If the gate_pin is associated to a hierarchical pin, this string specifies the name of the instance on which the hierarchical pin is instantiated. If the gate_pin isn't associated to any hierarchical pin, this attribute specifies the name of the instance on which the primitive module is instantiated.
parent_is_hard_module	Boolean that specifies whether the is_hard_module attribute is set to true on the parent module of the gate_pin. This attribute is false if the parent module of the gate_pin does not have the is_hard_module attribute set to true. This attribute is true for primitives instantiated directly into a design module which does not have is_hard_module set to true. This attribute can also be true for a gate_pin that has the hier_pin_name pointing to a pin on a module instantiated into a non-hard design module.
pin_index	Integer that specifies the *id* of the pin. This integer is identical to the second integer of the gate_pin’s *id* attribute. The pin index is persistent. The pin_index is the index of the gate_pin on the primitive module, where 0 is the index of the single output and integers larger than 0 correspond to the inputs.
primitive_name	Name of the primitive module associated with the gate on which the gate_pin exists. The primitive_name attribute values for all primitive types are listed in Table 3-1.
primitive_port_name	Name of the port on the primitive module. The primitive_port_name attribute values for all primitive types are listed in Table 3-1.
power_domain_name	Returns the name of the power domain in which the gate (instance) to which this gate_pin is attached exists. This attribute is inherited from the instance.
simulation_value	String that contains the simulation value on a gate_pin.

Built-In Primitives and Primitive Port Names

Table 3-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	**Outputs**
BUF	Buffer	I	O
INV	Inverter	I	O
AND	AND gate	I0, I1, …, In	O
NAND	Negated AND	I0, I1, …, In	O
OR	OR gate	I0, I1, …, In	O

Table 3-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	**Outputs**
NOR	Negated OR gate	I0, I1, …, In	O
XOR	Exclusive OR	I0, I1, …, In	O
NXOR	Negated Exclusive OR	I0, I1, …, In	O
DFF	D Flip-flop	S, R, CK (CK0, CK1, … CKn in case of multiple clock/data input pairs), D (D0, D1, ..., Dn in case of multiple clock/data input pairs)	Q
DLAT	D latch	S, R, CK (CK0, CK1, … CKn in case of multiple clock/data input pairs), D (D0, D1, ..., Dn in case of multiple clock/data input pairs)	Q
PI	Primary input	-	O
PO	Primary output	I	-
TIE0	Tie-0	I	O
TIE1	Tie-1	I	O
TIEX	Tie-X	I	O
TSD	Tri-state driver with active high at control input.	EN, D	O
BUS	Bus primitive. Drivers must include at least one TSH or switch gate.	I0, I1, …, In	O
ZVAL	Z converter gate, converts Z to X: dummy gate inserted between output of the gate taking Z and the binary gate input.	I	O
WIRE	Wire	I0, I1, …, In	O

Table 3-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	**Outputs**
MUX	Multiplexer	S, D0, D1	O
TIEZ	Tie-Z	I0, I1, …, In	O
NMOS	Switch gate	G (gate), S (source)	D (drain)
ZHOLD	Z-hold allows modeling of tri-state nets such that they can retain the previous state when the net goes to a Z value.	I	O
PBUS	Pull-bus gate. Used when combining strong (ZW) bus and weak bus signals (e.g. TIE0) together. The strong value (input 1) always goes to the output, unless the value is Z, in which case the weak value (input 2) propagates to the output.	I0, I1	O
WBUS	Weak bus primitive	I0, I1, …, In	O
BUFZ	Buffer allowing Z value at input.	I	O
XDET	X-detector gate: input ‘X’ results in output value ‘1’; otherwise output is ‘0’.	I	O

Table 3-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	**Outputs**
ZDET	Z-detector gate: input ‘Z’ results in output value ‘1’; otherwise output is ‘0’.	I	O
RAM	Read-write memory	S, R, WCK (WCK0, WCK1, … WCKw in case of multiple write ports), WEN (WEN0, WEN1, … WENw in case of multiple write ports), WADDR[0…i] (WADDR0[0…i], WADDR1[0…i], … WADDRw[0…i] in case of multiple write ports), WDIN[0…j] (WDIN0[0…j], WDIN1[0…j], … WDIN w[0…j] in case of multiple write ports), RCK, REN, RADDR[0…i] (RADDR0[0…i], RADDR1[0…i], … RADDRr[0…i] in case of multiple read ports)	Q
ROM	Read-only memory	CK, EN, ADDR[0…i] (ADDR0[0…i], ADDR1[0…i], … ADDRr[0…i] in case of multiple read ports)	Q
RAM_OUT	Output of a memory, place holder for multiple data outputs of memories in the flat model.	I0, I1, …, In	O
ROM_OUT	Output of a memory, place holder for multiple data outputs of memories in the flat model.	I0, I1, …, In	O

Table 3-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	Outputs
FB_BUF	Feedback buffer: internal gate type to break combinational loops in the design.	I	O
PGEN	Pulse generator: circuitry that creates a pulse at its output when active.	I	O
CORE	Core (obsolete)	I0, I1, …, In	O
CORE_OUT	Output of core, place holder for multiple core outputs in the flat model (obsolete).	I0, I1, …, In	O

Inheritance

Built-in inherited attributes:

- During flattening, attributes defined on hierarchical pins (cell or design) are copied to the gate_pin objects when there is a gate_pin associated to the hierarchical pin. Those are fault sites on cell pins, and those pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.

Related Commands

get_attribute_list	get_gate_pins
get_attribute_value_list	get_pins
report_attributes	get_name_list

Gate_pin Specification

A gate_pin object (gate_pin_object) is assigned a number ID rather than having an actual name. The number ID is a unique gate pin object id of the format "gate_id.gate_pin_id". For example an output of an AND gate in the flattened design might have an ID of “1325.0”.

ICL Data Model

The purpose of the Instrument Connectivity Language (ICL) is to describe the elements that comprise the 1687 network as well as their logical (though not necessarily physical) connections to each other and to the instruments at the endpoints of the network. ICL bears a loose resemblance to a hierarchical netlist such as Verilog; it is organized by modules that may contain instances of other modules, and it describes the connections between the pins of the instances. However, it is important to note that ICL is not a complete netlist; connections are port-to-port rather than through nets, and ICL freely uses abstraction in order to omit the detailed physical construction of the circuitry — only the behavioral operation of the network is represented.

Beyond merely documenting the structure of the network, the purpose of ICL is to enable an operation called “test pattern retargeting.” With test pattern retargeting, the sequences of test patterns, written in PDL, that are to be applied at the instrument boundaries are mapped through the IJTAG network to a higher level of hierarchy and ultimately to chip level pins. Tessent Shell reads and stores ICL information in a data structure and uses that information to retarget the instrument-level test patterns into test patterns that can then be applied at a higher level.

The ICL data model defines objects as one of the following four data types: icl_module, icl_instance, icl_port, and icl_pin. The icl_module and the icl_port object types are created as soon as ICL modules are read in using the read_icl command. Each icl_module object has its list of icl_port objects. Once the current design is set using the set_current_design command, the ICL data model is elaborated downward from the current design and icl_instance objects are created for each instance of icl_module, and icl_pin objects are created for each port of the modules associated to the icl_instances. The icl_instance and icl_pin objects are hierarchical objects and therefore only exist after the current design is set.

If a Verilog or Vhdl representation has also been read prior to issuing the set_current_design command, the port list on the design and the ICL module corresponding to the current design is compared to make sure that all ports declared in the ICL module also exist on the design module. The design module is allowed to have more ports that the ICL module. In fact, it is very likely the design module will have more ports because the ICL module only include the ports with an IJTAG function while the design module includes all ports on the physical module. The test bench created for the current design uses the complete port list read in from the design view when it is supplied.

ICL Object Types

The icl_module, icl_instance, icl_port, and icl_pin object types are described on the following reference pages.

icl_module

Description

One module is designated as the target module using the set_current_design command. Instances and pins are hierarchical objects defined relative to the current module.

The following properties apply to the icl_module object type:

- An icl_module object has a simple non-hierarchical name. Only one icl_module with a given name is allowed within a given namespace. Currently there is only one global namespace for ICL in Tessent Shell.
- An icl_module can be parameterized and its parameters can be overridden during instantiation. For each combination of parameter overrides, an icl_module object corresponding to the parameterized view exists. The name of the parameterized view is uniquified with a @PV# suffix where # is a unique integer starting from 1 and incrementing per unique parameterized view.
- One master icl_module exists for each module definition in the input files. The master icl_module is the one that contains the ICL module definition with default parameter values.
- Attributes defined on icl_modules are automatically visible as read-only attributes on the instance objects when the same attribute name is not also registered on the icl_instance object type.
- Attributes defined with the set_attribute_options -applies_to_child_instances switch set to On automatically become visible to all child instances of each instance of the icl_module.
- icl_module attributes are stored on all parameterized views of an icl_module. When an attribute value is set on an icl_module object, the attribute value is set on all icl_module objects having the same master_name within a name space.

For more information on attributes, see “Attributes” on page 103.

Built-In Attributes

The icl_module object type has the following attributes:

file_path_name	String that specifies the pathname to the file where a given module was read from. This attribute is null for modules created by ICL extract until they have been saved and read back in.
forced_high_input_port_list	Lists all input ports that were constrained to 1 during ICL extraction. Those constraints are automatically re-applied in the generated patterns. They are also verified to be properly simulated when running ICL extract at the next level. An I5 DRC violation is generated if the simulated value on any of those pins is not 1.

forced_high_internal_ input_port_list	Lists all internal pins that were constrained to 1 during ICL extraction. Those constraints are reported in this attribute for debugging and serve no other purpose.
forced_high_output_port_ list	Lists output ports of IJTAG instruments that must be forced high during ICL extraction in order to see all the connections between the instruments. You must use this attribute with care and typically use it for logictest testmode signals sourced by the ICL network itself. For example, if you have a TDR bit driving a TM signal and this TM signal puts the circuit in scan mode, you may need to force this signal to its inactive value for the rest of the ICL network to be traceable.
forced_low_input_port_ list	Lists all input ports that were constrained to 0 during ICL extraction. Those constraints are automatically re-applied in the generated patterns. They are also verified to be properly simulated when running ICL extract at the next level. An I5 DRC violation is generated if the simulated value on any of those pins is not 0.
forced_low_internal_ input_port_list	Lists all internal pins that were constrained to 0 during ICL extraction. Those constraints are reported in this attribute for debugging and serve no other purpose.
forced_low_output_port_ list	List output ports of IJTAG instruments that must be forced low during ICL extraction in order to see all the connections between the instruments. You must use this attribute with care and typically use it for logictest testmode signals sourced by the ICL network itself. For example, if you have a TDR bit driving a TM signal and this TM signals puts the circuit in scan mode, you may need to force this signal to its inactive value for the rest of the ICL network to be traceable.
icl_extraction_date	Reports the date and time when the ICL module was extracted. It is defined in the ICL module and created by ICL extraction.

ijtag_logical_connection	An attribute that creates a logical connection between source and destination ports. These attributes are transferred to the ijtag_logical_hier_connection_from_src and ijtag_logical_hier_connection_to_dst attributes on the matching module object. ICL extraction traces through those connections as if there was a buffer between the two ports. The syntax is attribute ijtag_logical_connection = "{src1 dst1} {src2 dst2} ..."; The source and destination ports may or may not be declared as ports in the ICL module but they must be declared with the proper direction in the design module object. To create a logical connection that is not between an input and output port of a module having an associated ICL module, use the add_ijtag_logical_connection command.
is_created	Boolean that specifies whether the module was created by ICL extraction. This attribute is set to true for modules created by ICL extraction. This attribute is not exported to the ICL file. Once the ICL module is re-read, this attribute is false.
is_modified	Boolean that specifies whether an ICL module contains attributes that have been added or modified after the module was read in.
is_valid	Boolean that specifies whether the ICL module is deleted or still valid. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
keep_active_during_scan_test	Boolean that specifies that the given ICL module is a node that must remain active during scan test so as not to be disturbed and be usable for scan test_setup. See the create_dft_specification command description for more information on how it is used.
line_number	Integer that specifies a line number in the file where a given module was read from. This attribute is null for modules created by ICL extract until they have been saved and read back in.
master_name	String that specifies the name of the icl_module without the optional parameterized view suffix.
name	String that specifies the name of the icl_module with an optional parameterized view suffix @PV#. ICL modules are defined from files read into the ICl database with the read_icl command. For example, the name of a parameterized view of the master icl_module ModA is: ModA@PV1
object_type	Returns the object data type “icl_module”.

partially_forced_input_port_list	Lists all bus ports with at least one element in the forced_low_input_port_list and forced_high_input_port_list. This attribute is useful when creating the testbench using the ICL port list in order to get the complete bus range of the constrained bused ports. This attribute is not used when the Verilog or VHDL design module is read before setting the current design in the patterns -ijtag context because the top-level port list is then extracted from the design module.
scan_interface_list	Lists all ScanInterface names defined within the ICL module.
tessent_dft_function	A string attribute used to identify an ICL module having special meaning during DFT. For example, the create_dft_specification command uses this attribute to identify the Sib(sti) and Sib(sri) so that they can be found again during the next insertion pass.
tessent_ignored_design_instances	A string attribute reported by ICL extract to reflect the list of design instances ignored during ICL extraction. These are the design instances with an ICL module for which the Boolean attribute ignore_during_icl_extraction has been set. The format of this attribute is a list of three-element lists as shown here: { {<IclModuleName>} {<DesignModuleName>} {<DesignInstancePath>} ... }
tessent_instrument_container	String that specifies the base name of the directory that contains the Tessent Instrument Description (TID) file and any other IP-specific data. This attribute is required for any ICL module that has IP-specific data.
tessent_instrument_type	String that identifies the ICL module as one of the known instrument types within Tessent Shell. This attribute is currently unused and is a provision for the open plug-in architecture being developed.
tessent_is_physical_module	Boolean that is set on the top ICL module when the extract_icl command runs and the level was set to chip or physical_block using the set_design_level command,
tessent_rtl_pre_trace_stop_port_list	Lists the names of ports on which the tool stops the ICL tracing during the ICL extraction pre-trace phase. This is useful to prevent the unnecessary synthesis of module during ICL extraction.
tessent_signature	A string that is used to identify that an ICL module as not been modified after its creation. An ICL module can be read in without a tessent_signature or with a valid tessent_signature but a module with an invalid signature generates an errors and is rejected during the read_icl command.

test_setup_procfile	Reports the filename of the procfile that contained the optional test_setup procedure used during ICL extraction. It currently is only informational to remind the user to reuse the same test_setup file during IJTAG pattern retargeting.
tessent_use_in_dft_ specification	String that you can set on an ICL module in its ICL file to force the create_dft_specification command to ignore instances of this module. The legal value is auto or false.

ICL Module Specification

An ICL module object is specified by an ICL module name which is a string. For example: “modA”.

icl_port

Description

The following properties apply to the icl_port object type:

- An icl_port object has a simple non-hierarchical name.
- An icl_ port is an object on an icl_ module and can have an input or output direction.
- One port object exists for each bit of a bused port so every bit of a bussed port can be attributed independently.
- Attributes defined on icl_port objects are automatically visible as read-only attributes on the associated icl_pin objects unless the attribute is also registered for the icl_pin object type.
- Attributes set on an icl_port of one icl_module are set on the same port of each icl_module having a common master_name. Because different parameterized views can have more or less icl_port objects when the size of a bussed icl_port is parameterized, attributes on the other icl_module having the common master_name are only copies if the port object actually exists on the given parameterized view.

For more information on attributes, see “Attributes” on page 103.

Built-In Attributes

The icl_port object type has the following attributes

active_polarity	String attribute that is defined on the port with the function Reset to reflect the ActivePolarity of the ResetPort in ICL.
bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.
bus_name	String that specifies the name of the bus without the index. <name> = bus_name [index] when is_bus is true; otherwise, bus_name is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether left_index is smaller, larger than, or equal to right_index.

connection_rule_option	Specified inside the Port wrappers of the ICL modules and used to modify the connection rules for the corresponding port. You use one of the following values to achieve the described behavior. • **allowed_no_source** — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations. • **allowed_tied** — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied high or low. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations. • **allowed_tied_low** — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied low. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations. • **allowed_tied_high** — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied high. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations. • **allowed_no_destination** — Allowed on output ports of an ICL instrument to indicate that this output port is allowed not to be connected to a valid destination. You typically use this for DataOutPort and ScanOutPorts of host ports which are not always used in all instantiations. • **auxiliary_data_enable** — Identifies the DataOutPort as an auxiliary data enable pin. When tracing a port with a forced_low_output_port_list or a forced_high_output_port_list attribute pointing to a port declared as an auxiliary_data_enable or auxiliary_data_enable_inverse, ICL extract asserts all ports on all instances declared as an auxiliary_data_enable or auxiliary_data_enable_inverse to their inactive values, except for the ones referenced by the current port which are forces to their active values instead. This enables ICL extract to extract DataOut ports connected through an AND OR mux like this: (d1 & en1) | (d2 & en2) | (d3 & en3);

connection_rule_option (continued...)	• **auxiliary_data_enable_inverse** — Identifies the DataOutPort as an auxiliary data enable inverse pin. • **must_connect_to_top_port** — Allowed on input and output ports of an ICL instrument to indicate that this input or output port is only allowed to be connected to a primary input or output pin of the current design. For example, a ScanInPort is allowed to be sourced by a ScanOutPort of another instance. If this attribute is set to must_connect_to_top_port, it is only allowed to be sourced by a primary input port.
default_load_value	This attribute corresponds to the DefaultLoadValue that is specified on DataIn ports in the ICL. Possible values are: 0, 1, or X, where X is specified when the DataIn port does not have a specified default load value.
direction	Direction of the icl_port. Possible values are: input or output.
forced_low_output_port_ list	This attribute is specified inside the Port wrappers of the ICL modules and is used to list output ports on the IJTAG instrument that must be force low during the tracing of the current output port. The listed ports are simulated low and appended to the stable_after_setup simulation condition when tracing the associated output port. For example, tdoEnable typically needs to be forced active when tracing the tdo port of a TAP controller.
forced_high_output_port_ list	This attribute is specified inside the Port wrappers of the ICL modules and is used to list output ports on the IJTAG instrument that must be force high during the tracing of the current output port. The listed ports are simulated high and appended to the stable_after_setup simulation condition when tracing the associated output port. For example, tdoEnable typically needs to be forced active when tracing the tdo port of a TAP controller.
freq_multiplier	A positive integer value attribute at the icl_port. The value is computed from the optional FreqMultiplier keyword of the ICL ToClockPort statement. The default value is 0.
freq_divider	A positive integer value attribute at the icl_port. The value is computed from the optional FreqDivider keyword of the ICL ToClockPort statement. The default value is 0.

function_modifier	A string with value CaptureShiftClock or CaptureShiftClockInv that can be specified on a ToCaptureEnPort and a CaptureEnPort in ICL. When specified to CaptureShiftClock or CaptureShiftClockInv on a CaptureEnPort, the port can only trace to ToCaptureEnablePort or a CaptureEnPort with function_modifier also set to CaptureShiftClock or CaptureShiftClockInv. When generating patterns for an ICL module and this module has a CaptureEnPort with function_modifier equal to CaptureShiftClock, the port is driven by a gated version of TCK that is only active during the capture and shift cycles. When generating patterns for an ICL module and this module has a CaptureEnPort with function_modifier equal to CaptureShiftClockInv, the port is driven by a gated version of inverted TCK that is only active during the capture and shift cycles.
ijtag_function	String that specifies the function of the icl_port; for example, “scan_in”. This is the ICL port function string converted to lowercase and the words connected with underscores.
index	Integer that specifies the index of the icl_port that is already part of the name when the icl_port is part of a bus.
is_bus	Boolean that specifies whether the icl_port is part of a bus. This attribute is set to true when the icl_port is part of a bus.
is_valid	Boolean that specifies whether the ICL port still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
launch_edge	String attribute that is defined on a port with function ScanOut to reflect the LaunchEdge of the ScanOutPort in ICL.
master_module_name	String that specifies the master_name of the icl_module object the icl_port belongs to.
module_name	String that specifies the name of the icl_module object the icl_port belongs to.
name	String that specifies the name of the icl_port including its bus index when it is an element of a bus.
object_type	Returns the object data type “icl_port”.
scan_interface_list	Lists all ScanInterface names that the port belongs to.
tessent_dft_function	A string attribute used to identify ICL ports having special meaning during DFT.
tessent_use_in_dft_ specification	String that you can set on an ICL Port in its ICL file to force the create_dft_specification command to ignore this DataIn or DataOut port. The legal value is auto or false.

Inheritance

Built-in attribute inheritance from associated icl_module objects:

- None

Port Specification

An ICL port object is an input, output, or inout interface of an ICL module, which is specified by a string. Examples of ICL port names are: “In1”, “ClkA”, and “Out3”.

icl_instance

Description

An icl_instance is a single instantiation of an icl_module. No icl_instance object exists until the set_current_design command is executed.

The icl_instance object type interacts with attributes as follows:

- Module attributes are automatically visible as read-only attributes on corresponding icl_instances if the icl_instance object type does not have the same attribute registered.
- Attributes defined with the applies_to_child_instances option set to On automatically become visible to all child instances of the icl_instance object.

For more information on attributes, see “Attributes” on page 103.

Built-In Attributes

The icl_instance object type has the following attributes:

is_valid	Boolean that specifies whether the ICL instance still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the name of the icl_instance (value of the name attribute) without the hierarchical path.
master_module_name	String that specifies the value of the master_name on the icl_module object associated with the icl_instance.
module_name	String that specifies the name of the ICL module associated to the icl_instance with the @PV# suffix when the instantiation uses parameter overrides.
name	String that specifies the full hierarchical instance path of the icl_instance with '.' as a hierarchy separator.
object_type	Returns the object data type “icl_instance”.
parent_instance	String that specifies the instance name of the ICL instance in which the pin is instantiated. It is null for pins on icl_instances found within the current design.
tessent_design_instance	An attribute populated by ICL extract when extracting the top level ICL module. The attribute reflects the design instance name corresponding to the ICL instance at the time of ICL extraction.

Inheritance

Built-in attribute inheritance from associated icl_module objects:

- c0_constrained_internal_pin_list

- c0_constrained_pin_list
- c1_constrained_internal_pin_list
- c1_constrained_pin_list
- icl_extraction_time
- is_created
- partially_constrained_bus_pin_list
- port_group_list
- tessent_instrument_type
- test_setup_procfile

Related Commands

get_attribute_value_list	get_name_list
get_icl_instances	report_attributes

ICL Instance Specification

An ICL instance object is specified by a complete hierarchical ICL instance pathname. For example: “/u1/u2/u3”.

icl_pin

Description

An icl_pin is an object on an icl_instance that can be connected to other icl_ pin or icl_port objects. No icl_pin object exists until the set_current_design command is executed.

The icl_pin object type interacts with attributes as follows:

- Attributes defined on icl_port objects are automatically visible as read-only attributes on the associated icl_pin objects unless the attribute is also registered for the icl_pin object type. This is the case for the name attribute which is defined for both icl_port and icl_pin object types.

For more information on attributes, see “Attributes” on page 103.

Built-In Attributes

The icl_pin object type has the following attributes

base_name	String that specifies the name of the pin without the leaf name.
freq_multiplier	A positive integer value attribute at the icl_pin. The value is computed from the optional FreqMultiplier keyword of the ICL ToClockPort statement. The default value is 0.
freq_divider	A positive integer value attribute at the icl_pin. The value is computed from the optional FreqDivider keyword of the ICL ToClockPort statement. The default value is 0.
is_valid	Boolean that specifies whether the icl_pin still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the name of the ICL pin (value of the name attribute) without the hierarchical path.
name	String that specifies the full hierarchical name of the icl_pin with '.' as a hierarchy separator.
object_type	Returns the object data type “icl_pin”.
parent_instance	String that specifies the name of the parent icl_instance of the icl_instance on which the icl_pin is on.
tie_value	String that indicates the value to which the port is tied. Possible values are: 0, 1, X, or “” (empty string). The default is the empty string which means the port is not tied to a value.

Inheritance

Built-in attribute inheritance from associated icl_port objects:

- bus_left_index

- bus_name
- bus_range_direction
- bus_right_index
- bus_width
- direction
- ijtag_function
- index
- is_bus
- master_module_name
- module_name
- port_group_list

Related Commands

get_icl_fanins	get_name_list
get_icl_fanouts	report_attributes
get_icl_pins	report_ijtag_logical_connections
get_icl_instances	

Pin Specification

An ICL pin object is specified by a complete hierarchical ICL pin pathname including the ICL pin. For example: /u1/u2/u3/Y refers to pin Y of the hierarchical instance /u1/u2/u3.

Chapter 4
Attributes

Attributes are properties assigned to any object type. Attributes have names and values to associate relevant data with those objects. Attribute names may only include alphanumeric and underscore characters. This section provides information on the following topics:

Attribute-Related Commands 103
Attribute Types 104
Attribute Value Types 104
Attribute Filtering Equation Syntax 105
Glob and Regular Expression Pattern Matching Syntax 107
Matching Hierarchical Names With Escaped Identifiers 111

For detailed information on the attributes associated with each object type, see "Data Models" on page 57.

Attribute-Related Commands

You can use the set of Tessent Shell commands presented in Table 4-1 to create, manipulate, and query objects' attributes.

Table 4-1. Commands for Manipulating Attributes

Command	Description
get_attribute_list	Returns an alphabetically sorted Tcl list of attribute names.
get_attribute_option	Retrieves the current setting of an attribute's option.
get_attribute_value_list	Retrieves the value of an attribute on the specified design objects.
get_name_list	Returns the name(s) of the specified object(s).
register_attribute	Registers a new user-defined attribute.
report_attributes	Creates a human readable report for the set of attributes based on the usage options.
reset_attribute_value	Resets an attribute to its default value for the design objects specified in obj_spec.
set_attribute_options	Modifies options of any registered user-defined attribute.
set_attribute_value	Sets an attribute's value for the objects specified in object_spec.

Table 4-1. Commands for Manipulating Attributes

Command	Description
unregister_attribute	Unregisters a user-defined attribute that was registered using the register_attribute command.

Attribute Types

Tessent Shell supports two types of attributes: pre-defined attributes and user-defined attributes. Different object types have different pre-defined attributes. You can also create and specify user-defined attributes.

Pre-Defined Attributes

Pre-defined attributes exist on the object itself in the internal database. Because of this, pre-defined attributes do not need to be registered. Different object types have different pre-defined attributes. By default, these attributes are read-only.

Each data model has a list of pre-defined attributes which are described in sections "Hierarchical Design Data Model", "Flat Design Data Model", and "ICL Data Model". All data models will be exposed in subsequent releases of Tessent Shell and their associated built-in attributes will be documented.

User-Defined Attributes

User-defined attributes are registered with the register_attribute command before they can be used. The registration operation defines the attribute's value type and its default value and determines which design object type the attribute belongs to.

Attribute Value Types

Attribute values can have the following types:

Table 4-2. Attribute Value Types

Type	Description
Boolean	Case-insensitive. A Boolean. • Accepts any of the following for true: 1, true, yes, on. • Accepts any of the following for false: 0, false, no, off
Integer	Case-insensitive. An integer.
Double	Case-insensitive. Double-precision floating-point number.
String	Case-insensitive. A sequence of alphanumeric characters.

Attribute Filtering Equation Syntax

An attribute filtering equation is a series of relations joined together with the && (AND) and || (OR) operators. Parentheses are also supported. A basic relation compares or matches the value of an attribute with a constant expression through a relational operator.

Relational Operators

The relational operators are:

==	Equal
!=	Not equal
>	Greater than
<	Less than
>=	Greater than or equal to
<=	Less than or equal to
=~	Matches pattern
!~	Does not match pattern

Basic Relational Rules

The basic relational rules are as follows:

- Compare string attributes using any operator.
- Do not compare numeric attributes using pattern matching operators (=~ or !~).
- Compare Boolean attributes using only == and !=. The only possible value is true or false.
- Using an attribute without a relational operator in an equation is equivalent to saying att == true for a Boolean attribute or att != <defaultValue> for other types. You can also invert this default behavior by putting a ! in front of the attribute name. For example:

  ```
  is_something && !is_something_else
  ```

  translates to:

  ```
  is_something != <default> && is_something_else == <default>
  ```

  which mean the following when the attributes are of Boolean type:

  ```
  is_something == true && is_something_else == false
  ```

Pattern Matching in the Filtering Attribute Equation

By default, the =~ and !~ filter operators use simple wildcard pattern matching (glob) with the "*" and "?" wildcards. When the -regexp option is specified for any command, the complete Posix Extended Regular Expression syntax is supported.

When you use the -regexp option, you should pay special attention to how you quote filter expressions. We recommend using rigid quoting with braces around regular expressions.

Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expression as necessary.

Refer to "Glob and Regular Expression Pattern Matching Syntax" for a complete description of the Tessent Shell pattern matching mechanism and a detailed description of the regular expression syntax.

Filter Equation Examples

This example shows different filtering attribute equations used to filter instance objects:

```
register_attribute -name Att1 -value_type boolean
register_attribute -name Att2 -value_type integer -default -1
register_attribute -name Att3 -value_type string -default ""

set_attribute_value u1 -name Att1
set_attribute_value u1 -name Att2 -value 3
set_attribute_value u1 -name Att3 -value "aba"

set_attribute_value u2 -name Att1
set_attribute_value u2 -name Att3 -value "abb"

#Matches only u1 because Att2 has default value on u2 so Att2 returns
#false
get_instance -filter {Att1 && Att2}

{u1}

#Matches both because Att3 starts with a in both
get_instance -filter {Att1 && Att3 =~ "a*"}

{u1 u2}

#Matches u2 because Att2 defaults to -1.
get_instances -filter {Att2 < 2}

{u2}
```

Glob and Regular Expression Pattern Matching Syntax

The introspection commands perform pattern matching in two distinct ways with subtle usage differences. The first way is with the *name_patterns* argument and it is specified as a list of patterns to match against object names. The second one is the use of the =~ and ~! operators within a filter attribute equation.

When specifying name_patterns, the hierarchy separator (/) is used to automatically split the matching patterns so that each pattern can be matched against the leaf name of each level of hierarchy separately. For example, the command “get_instance a*/b*” means to match the leaf instance starting with b in each instance whose name starts with a. Refer to section “Matching Hierarchical Names With Escaped Identifiers” for ways to deal with that in the presence of escape identifiers, especially when the escaped identifiers contains slashes.

When specifying the filter attribute equation, the / is treated as a literal within the pattern and the entire value of the attribute is searched by the entire pattern. For example, the command “get_instance -filter {name =~ “a*/b*”}” would match instance a1/b1 as well as a1/c1/b1 because a* matches “1/c1” as the / is just another literal character to match.

In regular expressions syntax, most characters are treated as literals. That is, they match only themselves (e.g., a matches “a”). The exceptions are called meta characters and are listed in Table 4-3.

Table 4-3. Posix Extended Regular Expression Metacharacters

Meta Character	Description
.	The dot matches any single character.Within bracket expressions, the dot character matches a literal dot. For example: a.c matches “abc” and so on but [a.c] matches only “a”, “.”, or “c”.
[ ]	A bracket expression. Matches a single character that is contained within the brackets. For example, [abc] matches “a”, “b”, or “c”. [a-z] specifies a range which matches any lowercase letter from “a” to “z”. These forms can be mixed: [abcx-z] matches “a”, “b”, “c”, “x”, “y”, or “z”, as does [a-cx-z]. The - character is treated as a literal character if it is the last or the first character within the brackets: [abc-], [-abc]. Note that backslash escapes are not allowed. The] character can be included in a bracket expression if they are the first character: []abc]. The [character can appear anywhere.
[^]	Matches a single character that is not contained within the brackets. For example, [^abc] matches any character other than “a”, “b”, or “c”. [^a-z] matches any single character that is not a lowercase letter from “a” to “z”. As above, literal characters and ranges can be mixed.

Table 4-3. Posix Extended Regular Expression Metacharacters

Meta Character	Description
^	Matches the starting position of the string. In Tessent shell, all matching is rooted which means the ^ character is inferred at the beginning of every expression when it is not already specified. For example, abc.* is equivalent to ^abc.* and both mean to match any string starting with abc.
$	Matches the ending position of the string. In Tessent shell, all matching are rooted which means that the $ character is inferred at the end of every expression when it is not already specified. For example, .*abc is equivalent to .*abc$ and both mean to match any string ending with abc.
( )	Defines a marked expression. The string matched within the parentheses can be recalled later (see next entry, \n). A marked expression can also be used to specify a sequence of characters that must be matched some number of times by following it by a *, + or {m.n} sequence. For example, (ab)* matches “”, “ab”, “abab”, “ababab”, and so on.
\n	Matches what the nth marked expression matched, where n is a digit from 1 to 9. For example (ab).*\1 matches any string that starts and ends with either a or b, such as aa, aca, aba, or bab but not acb and bca. A second example (ab)(cd).*\2\1 matches acffca but not acffaa because the second marked expression matched c and the first matched a.
*	Matches the preceding element zero or more times. For example: ab*c matches “ac”, “abc”, “abbbc”, and so on. [xyz]* matches “”, “x”, “y”, “z”, “zx”, “zyx”, “xyzzy”, and so on. (ab)* matches “”, “ab”, “abab”, “ababab”, and so on.
?	Matches the preceding element zero or one time. For example: ba? matches “b” or “ba”.
+	Matches the preceding element one or more times. For example: ba+ matches “ba”, “baa”, “baaa”, and so on.
|	The choice operator matches either the expression before or the expression after the operator. For example: abc|def matches “abc” or “def”.
{m,n}	Matches the preceding element at least m and not more than n times. For example: a\{3,5\} matches only “aaa”, “aaaa”, and “aaaaa”. (ab){2,3} matches “abab” and “ababab”.

Table 4-4 the escapes character that have special meaning in Posix regular expression syntax:

Table 4-4. Special Characters in Regular Expressions

Escaped character	Description
\f	Form Feed
\n	New Line
\r	Carriage Return
\t	Tab

Table 4-5 lists the pre-defined special character sets that can be used in regular expressions:

Table 4-5. Special Characters Set in Regular Expression

Symbol	Content	Description
[:alnum:]	[A-Za-z0-9]	Alphanumeric characters
[:alpha:]	[A-Za-z]	Alphabetic characters
[:blank:]	[\t]	Space and tab
[:cntrl:]	[\x00-\x1F\x7F]	Control characters
[:digit:]	[0-9]	Digits
[:graph:]	[\x21-\x7E]	Visible characters
[:lower:]	[a-z]	Lowercase letters
[:print:]	[\x20-\x7E]	Visible characters and space character
[:punct:]	[\]\[!#$%&'()*+,./:;<=>?@\^_`{|}~-]	Punctuation characters
[:space:]	[\t\r\n\v\f]	Whitespace characters
[:upper:]	[A-Z]	Uppercase letters
[:xdigit:]	[A-Fa-f0-9]	Hexadecimal digits

Example 1

The following list of examples illustrates the use of meta characters in matching expressions:

- .at matches any three-character string ending with “at”, including “hat”, “cat”, “bat”.
- [hc]at matches “hat” and “cat”.
- [^b]at matches all strings matched by .at except “bat”.
- ^[hc]at matches “hat” and “cat”, but only at the beginning of the string or line.
- [hc]at$ matches “hat” and “cat”, but only at the end of the string or line.

- \[.\] matches any single character surrounded by “[” and “]” since the brackets are escaped. For example: “[a]” and “[b]”.
- [hc]+at matches “hat”, “cat”, “hhat”, “chat”, “hcat”, “ccchat”, and so on, but not “at”.
- [hc]?at matches “hat”, “cat”, and “at”.
- [hc]*at matches “hat”, “cat”, “hhat”, “chat”, “hcat”, “ccchat”, “at”, and so on.
- cat|dog matches “cat” or “dog”.
- [[:digit:]]+ matches “1”, and “32” but not “a1”.

Example 2

The following example matches all leaf instance names between 3 and 4 characters in length.

get_instances -filter { leaf_name =~ “[[:alnum:]_]{3,4}”} -regexp

```
{u1/u2/abc u1/u3/ab_1}
```

Example 3

The following example matches all instances having a leaf instance name with a prefix matching the value within a Tcl variable followed by 1 or many digits. In the example, the attribute equation cannot be enclosed in braces because it would prevent the Tcl shell from replacing the Tcl variable. Instead, the attribute equation is enclosed in double quotes and all special characters within the expression are escaped.

set prefix “MyString_”
get_instances -filter “leaf_name =~ \”${prefix}\[\[:digit:\]]\]+\ “” -regexp

```
{u1/u3/MySting_1 u1/u2/MySting_75}
```

Example 4

The following example looks for all leaf instances with a prefix equal to abc inside all instances starting with u or U followed by one or more digits. Notice that the / is automatically inferred as a hierarchy separator causing the expression to be split in two and applied to each level of hierarchy separately.

get_instance {[Uu][[:digit:]]+/abc.*} -regexp
{u3/abcd U43/abc}

Matching Hierarchical Names With Escaped Identifiers

As described in "Glob and Regular Expression Pattern Matching Syntax" on page 107, the slashes inside a name_patterns argument have special meaning; they are interpreted as hierarchy separators unless they are within escaped identifiers. For example, consider an instance whose name has two escaped identifiers as part of its hierarchical name: "u1/\u2/u3 /\u4/u5 /insta". In Tessent Shell, all attribute, introspection, and editing commands can reference such a name with and without the escape characters and trailing spaces.

Note

Legacy commands (commands that existed prior to v9.6) only support names from which the escape characters and trailing spaces have been removed. However, the legacy commands are upgraded to accept collections of objects instead of a simple list of names so you can pass in directly the output of commands such as get_pins and get _instances.

When the escape identifier and trailing spaces are removed, the example path "u1/\u2/u3 /\u4/u5 /insta" becomes "u1/u2/u3/u4/u5/insta". As you can see, the four levels of hierarchy appear as six levels because the leaf instance names \u2/u3 and \u4/u5 look like two levels each.

Matching "u1/u2/u3/u4/u5/insta" against "u1/\u2/u3 /\u4/u5 /insta" requires searching for u1/\u2/u3 if no matches are found for u1/u2. You must apply this guessing approach recursively which can be expensive when the escaped identifiers contain many slashes. More importantly, pattern matching on these names is difficult because the / is interpreted as a hierarchy separator which incorrectly splits the name_patterns into the wrong patterns to match against the level of hierarchies. For these reasons, we recommend you keep the escape identifiers in the name_patterns argument to prevent escaped slashes from being interpreted as hierarchy separators.

The following two examples both successfully match the instance with name "u1/\u2/u3 /\u4/u5 /insta":

```
get_instances {{u1/\u2/u3   /\u4/u5 /insta}}
get_instances {{u1/\\u[0-9]+/u[0-9]+   /\\u[0-9]+/u[0-9]+   /insta}} -regexp
```

Because the get_instances command accepts a list of pattern names as input, two sets of braces are used to enclose the name_patterns argument. The Tcl shell performs a first evaluation to get the list items and consumes one set of braces; it performs a second evaluation on each item and consumes the second set of braces. Without two sets of braces, you would need to escape both bracket characters "[" and "]" to keep them as part of the regular expression and prevent them from being interpreted as a Tcl command. Notice how the \ that is part of the escaped identifier is escaped by a second \ when the -regexp option is used. This is because the \ is a special character in Posix regular expression syntax and it must be escaped to be treated as a literal.

In the second example, “get_instances {{u1/\\u[0-9]+/u[0-9]+ /\\u[0-9]+/u[0-9]+ /insta}} -regexp”, the *leaf instance* matching insta, inside leaf instances matching “\u[0-9]+/u[0-9]+”, inside leaf instances matching “\u[0-9]+/u[0-9]+”, inside leaf instance matching u1 is returned. Notice how the slashes within the escaped identifiers were not interpreted as hierarchy separators but as literals within the patterns.

The parser terminates the escape identifier string when it encounters a white space. For this reason, your patterns must not include any spaces; there is no reason to include spaces when matching instance path names.

If you need the Tcl shell to replace the Tcl variable within the regular expression, as in the example below, you must use double quotes instead of the inner set of braces and escape every special character. The \\ became \\\\ because the Tcl interpreter will replace \\\\ by \\, and the \\ will be interpreted as a \ literal by the regexp parser.

Having to escape all special characters is very error prone. We recommend that you use the double sets of braces as shown above unless your pattern contains Tcl variables that must be replaced by the shell as shown below.

```
set range “0-9”
get_instances {“u1/\\\\u\[$range\]+/u\[$range\]+ /\\\\u\[$range\]+/u\[$range\]+ /insta”} \
        -regexp
```

Chapter 5
Configuration-Based Specification

DftSpecification Configuration Syntax

This chapter describes the configuration data syntax used inside Tessent Shell to specify DFT components that are to be built and, optionally, inserted into a design. This chapter only covers the IjtagNetwork wrapper as it exists inside the DftSpecification wrapper. In subsequent releases, support for additional wrappers such as the OCC, MemoryBist, and BoundaryScan wrappers will be added and documented here. Eventually, it will be possible to specify a wide variety of DFT specifications, in a single wrapper or in multiple DftSpecification wrappers, to generate and insert any type of instrument in one or multiple insertion passes.

This interface is designed to be open and flexible. Not only will all of Mentor Graphic DFT instruments become available within Tessent Shell; any third-party provider (including end user in-house instruments) will be able to integrate their instrument types into the Dft specification process. This will enable chip designers to benefit from a unified yet flexible platform capable of defining and inserting test-related instruments from an infinite amount of sources into their designs.

This chapter uses the syntax conventions in Table 5-1 and Table 7-1 on page 341 when documenting wrappers and properties used in configuration data.

Table 5-1. Syntax Conventions for Configuration Files

Convention	Example	Usage
Italic	scan_in : *port_pin_name*;	An italic font indicates a user-supplied value.
Underline	wgl_type : <u>generic</u> | lsi**;**	An underlined item indicates the default value.
|	logic_level : <u>both</u> | high | low;	The vertical bar separates a list of values from which you must choose one. Do not include the bar in the configuration file.
...	port_naming : *port_naming*, ...;	Ellipses indicate a repeatable value. The comment “// repeatable” also indicates a repeatable value.
//	// default: ijtag_so	The double slash indicates the text immediately following is a comment and tells the tool to ignore the text.

DftSpecification

Syntax

```
DftSpecification(module_name,id) {
  rtl_extension               :  string;  // default: v
  gate_extension              :  string;  // default: vg
  reuse_modules_when_possible :  on | off |auto;

  IjtagNetwork {

  }
  //Other instrument types to be added in future release
}
```

Description

A wrapper that specifies the information used by the process_dft_specification command to build a series of instruments and, optionally, insert them into a design.

As shown in the syntax section above, this release only supports the IjtagNetwork specification. All instrument types supported by Tessent Shell will be migrated into this wrapper in subsequent releases. The ability to plug third-party instruments into the DftSpecification and have them fully supported by the process_dft_specification command will also be made available.

The DftSpecification wrapper is uniquely named using two strings. The first string is the *module_name* of the design the DFT specification is for. The second string is a general purpose *id* that differentiates multiple DFT specifications for a given design module where each DftSpecification is for a different insertion pass.

Parameters

- *module_name*

  A string that identifies the design that the DFT specification is for. When running the process_dft_specification command, the name of the current design must match this string unless the -no_insertion option is specified with this command; if the -no_insertion option is used, it can also be specified using the -design_name design_name option.

- *id*

  A string that identifies which insertion pass the DFT specification is to be used for. When executing the process_dft_specification command, the id argument of the command is used to specify this id used in the DftSpecification name. If only one DftSpecification wrapper for a given module_name is loaded in memory, the process_dft_specification command uses it even if the id is not specified as an option. Using either “rtl” or “gate” as the id string is a good strategy to identify the instruments inserted in the RTL and those inserted in the synthesized netlist.

- rtl_extension : *string*;

  A string that specifies the extension used when writing out files containing Verilog RTL descriptions of the created instruments. The string must start with a letter and may be followed by any number of letters, numbers, underscores, and periods. The value of rtl_extension must be different than the value of gate_extension. The default value when unspecified is “v”.

- gate_extension : *string*;

  A string that specifies the extension used when writing out files containing gate-level Verilog modules. This extension is used in the synthesis script of the instruments and when writing out the concatenated netlist. The gate_extension is only relevant in the -no_rtl context. The string must start with a letter and may be followed by any number of letters, numbers, underscores, and periods. The value of gate_extension must be different than the value of rtl_extension. The default value when unspecified is “vg”.

- reuse_modules_when_possible : on | off | auto;

  A Boolean that specifies whether instrument modules should be reused if possible, or if different modules should be created for each instance. When the value is auto, it is considered to be On in the rtl context and Off in the no_rtl context. When inserting instruments into a netlist, it is customary to avoid repeated instances of any module as timing optimization requires them to be uniquified. The default value is auto.

IjtagNetwork

Syntax

```
DftSpecification(module_name,id) {
  IjtagNetwork {
    DataInPorts {
    }
    DataOutPorts {
    }
    HostScanInterface (id) {            // repeatable
      Interface{ *DefSpec
      }
      DesignInstance(instance_name) {   // repeatable
      }
      ScanMux(id) {                     // repeatable
      }
      Sib(id) {                         // repeatable
      }
      Tdr(id) {                         // repeatable
      }
      Tap(id) {                         // repeatable
      }
    }
  }
}
```

Description

A wrapper that specifies the IJTAG network to be built and, optionally, inserted into the design.

This wrapper can be specified once for each DftSpecification wrapper. As illustrated in the syntax above, the IjtagNetwork specification consists of one DataInPorts wrapper, one DataOutPorts wrapper, and one or more HostScanInterface wrappers.

A HostScanInterface wrapper defines a scan interface below which a network of IJTAG nodes are serially accessible. The HostScanInterface/Interface wrapper is used to specify the end points of the HostScanInterface. By default, the wrapper defines a set of ports that may or may not already exist on the current design, but you can also use this wrapper to specify how to connect to an existing host interface present inside the design. For more details and example usage, see the description of the HostScanInterface/Interface wrapper. If the HostScanInterface/Interface wrapper only consists of ports on the current design, the add_icl_scan_interfaces and the set_icl_scan_interface_ports commands are issued during insertion such that, if you perform ICL extraction once you are done with insertion, the ScanInterface in the extracted ICL module will be named using the id of the HostScanInterface you specified in the DftSpecification.

The other five wrappers, DesignInstance, ScanMux, Sib, Tap, and Tdr define nodes serially connected below the HostScanInterface. They can be specified in any order, and they are all repeatable; however, their relative order defines the scan path connectivity. The scan-out of the first element declared in the HostScanInterface wrapper sources the scan-out port of the HostScanInterface. The scan-in port of the last element declared in the HostScanInterface wrapper is sourced by the scan-in port of the HostScanInterface.

The SIB, ScanMux, and TAP nodes become host interfaces to the client interfaces of the nodes declared inside them. See the description of the Sib, and ScanMux, Tap wrappers for more details. The example below illustrates the hierarchical nature of the IJTAG network.

Scan Testability of the IJTAG Network

Elements of the IJTAG network can be used to configure the circuit in its various scan modes. The example shown in Figure 5-1 illustrates the use of a TDR to generate the various scan mode signals. In this example, the portion of the network that gives access to this TDR must remain active during scan test and must remain unaffected by the scan test modes like any other test_setup hardware you may use. If the property keep_active_during_scan_test is set on a node, the host access path to the node is traced and every node in the access path is marked with the keep_active_during_scan_test attribute. The ICL modules are generated with this attribute and collected into the merged ICL file created by ICL extract. You can later use this information to declare those modules as non-scan during scan insertion, and force them to be kept in the graybox during graybox generation.

When the *id* of a Tdr wrapper is named “scan_modes”, the keep_active_during_scan_test property defaults to on for that TDR. This, in turn, forces all nodes needed to access it from the HostScanInterface to have keep_active_during_scan_test set to on.

Once you have extracted the final ICL using ICL extract, executing the command “get_icl_instances -filter keep_active_during_scan_test” will generate a collection of all ICL instances having keep_active_during_scan_test set to on. You can then use the tessent_design_instance attribute on the ICL instances to find the corresponding design instances and pass this list to your scan insertion and/or graybox generation step. For a complete list of attributes available on the ICL instance object type, see the icl_instance data model.

Parameters

None.

Example

The following example shows the DftSpecification of a simple IJTAG network having two SIBs connected in series; the first SIB hosts a design instance, and the second SIB hosts a TDR which in turn sources and observes the data signals of a second design instance. The example assumes the design already includes those two design instances and that an ICL file describing their ports exists for each of them.

The instance “u1/bottom_green” is an instance of module ModB and has a single ScanInterface described in its ICL file; its ScanInterface will be hooked up to the host interface of the red SIB.

The instance “u2/top_green” is an instance of module ModA and has four DataInPorts and two DataOutPorts described in its ICL file. The DataOutPorts of the pink TDR is connected to the DataInPorts of ModA and vice versa. See the description of the DesignInstance wrapper for information about how the ICL files are automatically searched and matched to the design instance during the set_current_design invocation.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
```

```
        Sib(orange) {
          Tdr(pink) {
            DataOutPorts {
              connection(0)    : u2/top_green/en;
              connection(3:1) : u2/top_green/mode[2:0];
            }
            DataInPorts {
              connection(0) : u2/top_green/go;
              connection(1) : u2/top_green/done;
            }
          }
        }
        Sib(red) {
          DesignInstance (u1/bottom_green) {}
        }
      }
    }
  }
```

DesignInstance

Sib

ScanMux

Tdr

DesignInstance

Syntax

```
IjtagNetwork
  HostScanInterface(id) {
    DesignInstance(instance_name) {
      scan_interface : scan_interface_name;
    }
  }
}
```

Description

A wrapper that references an instance in the design that has a ScanInterface to connect to.

The *instance_name* string is a design instance name relative to the current design. When the process_dft_specification command is executed without the -no_insertion option, the tool verifies that the specified *instance_name* exists within the design. The tool also verifies that the associated design module has a matched ICL module with at least one ScanInterface in it. If there is only one scan interface in the ICL module, you do not need to specify the scan_interface property, but if there is more than one ScanInterface, you must use the scan_interface property to identify which one to connect to.

ICL modules are automatically searched and matched to the design modules when the set_current_design command is executed. The search paths for the ICL files are specified using the set_design_sources -format icl command. The module name matching rules are specified using the set_module_matching_options command.

Parameters

- instance_name

  A string that refers to a design instance relative to the current design.

- scan_interface : *scan_interface_name;*

  A property that is used only when the referenced design instance is an instance of a module having more than one ScanInterface declared in its ICL module. You must repeat the DesignInstance wrapper for each *scan_interface_name* found in the ICL module, if you want to connect all of them to the network.

  If you have a design instance with multiple scan interfaces and they share a common scan-in port, you cannot connect them to a SIB because this would required independent scan-in ports. Instead, you must connect them all to inputs of a scan mux, so that you end up with one scan-in port and one scan-out port. This is illustrated in the example that follows.

Example

The following example illustrates connecting the ScanInterface of a DesignInstance to a SIB. It also shows how a design instance that has three scan interfaces sharing a common scan-in port is first connected to two scan multiplexers before being connected to a SIB.

The select of the multiplexers are sourced by the DataOutPorts of the orange TDR which automatically sets its output_timing setting to “ijtag_scan_selection”. For a description and impact of this setting, see the Tdr wrapper description and specifically the “Update Stage Timing” section.

This example also shows the use of ScanMux in the network. It provides a hint about the backward propagation of the select signal though the selected path of the multiplexer. For a complete description of the ScanMux and the backward propagation of the select signals, refer to the ScanMux wrapper description section.

```

    }
  }
}
```

Description

A wrapper used to customize the interface of the HostScanInterface.

By default, the HostScanInterface connects directly to ports on the current design and follows the default naming shown in the syntax summary above. Those ports may or may not already exist in the current design. If they are not already present, they are created during insertion if the design level is set to "physical_block" or "sub_block". If the design level is set to “chip”, ports need to already exist and be connected to pad cells. For more information, see the set_design_level and read_cell_library commands.

You can also specify internal pins to connect the HostScanInterface to an existing host interface already present in the design. Example 1 shows how the Interface wrapper is used to create top-level ports, and to hook up to an existing host port. Example 2 shows how to hook up a SIB to a TAP inserted by ETAssemble in the LV Flow.

When connecting to an internal pin, specifying the reset_polarity of the reset pin is required; otherwise, you will get an ICL extract violation later on if the assumed value is not consistent with the actual reset polarity. If specified as auto, reset_polarity is determined by counting the number of children with an active high and an active low reset polarity and taking the polarity of the larger count.

Parameters

- design_instance : *instance_name*;

  This property defines the HostScanInterface on a ScanInterface defined in an ICL module associated to an instance in the design. The specified *instance_name* must be the name of an instance that already exists in the design, and it must be the instantiation of a module having a corresponding ICL module.

  ICL modules are automatically searched and matched to the design modules when the set_current_design command is executed. The search paths for the ICL files are specified using the set_design_sources -format icl command. The module name matching rules are specified using the set_module_matching_options command.

  A design_instance cannot be specified when process_dft_specification is run using the -no_insertion option.

- scan_interface : *id*;

  This property specifies which ScanInterface to define the HostScanInterface on when the design_instance property points to an instance associated to an ICL module having more than one ScanInterface. If the associated ICL module only has one ScanInterface, the scan_interface property is not needed.

  If the referenced ScanInterface is a client ScanInterface, the host ScanInterface is defined in such a way that the inserted IJTAG nodes will end up in front of and in series with the referenced client ScanInterface. If the referenced ScanInterface is a host ScanInterface, the the inserted IJTAG nodes will connect to it. This varying behavior based on the fact that the ScanInterface is of type host or client is illustrated in Example 1.

- tck : *port_pin_name;*

  This property defines the port or the pin name to source the IJTAG TCKPort function. The default is “ijtag_tck”.

- reset : *port_pin_name;*

  This property defines the port or the pin name to source the IJTAG ResetPort function. The default is “ijtag_reset”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- select : *port_pin_name;*

  This property defines the port or the pin name that is to source the IJTAG SelectPort function. The default is “ijtag_sel”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- shift_en : *port_pin_name*;

  This property defines the port or the pin name that is to source the IJTAG ShiftEnPort function. The default is “ijtag_se”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- capture_en : *port_pin_name;*

  This property defines the port or the pin name that is to source the IJTAG CaptureEnPort function. The default is “ijtag_ce”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- update_en : *port_pin_name;*

  This property defines the port or the pin name that is to source the IJTAG UpdateEnPort function. The default is “ijtag_ue”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- scan_in : *port_pin_name*;

  This property defines the port or the pin name that is to source the IJTAG ScanInPort function. The default is “ijtag_si”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- scan_out : *port_pin_name;*

  This property defines the port or the pin name to receive the IJTAG ScanOutPort function. The default is “ijtag_so”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- reset_polarity : active_high | active_low | <u>auto</u>;

  This property defines the polarity of the ResetPort. When set to auto, the reset_polarity is determine by counting the number of children with an active high or an active low reset port and taking the polarity of the larger count. When the reset property points to an existing reset pin, it is required to specify the reset polarity consistent with the source being used. Failing to specify the proper polarity results in a subsequent ICL extraction DRC violation. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- trst : *port_pin_name*;

  This property defines the port or the pin name that is to source the IJTAG TRSTPort function. The default is “trst”. This property is only used when the HostScanInterface is for a TAP scan interface.

- tms: *port_pin_name;*

  This property defines the port or the pin name to receive the IJTAG TMSPort function. The default is “tms”. This property is only used when the HostScanInterface is for a TAP scan interface.

- tdi : *port_pin_name*;

  This property defines the port or the pin name that is to source the IJTAG ScanInPort function. The default is “tdi”. This property is only used when the HostScanInterface is for a TAP scan interface.

- tdo : *port_pin_name;*

  This property defines the port or the pin name to receive the IJTAG ScanOutPort function. The default is “tdo”. This property is only used when the HostScanInterface is for a TAP scan interface.

- tdo_en : *port_pin_name;*

  This property defines the port or the pin name to receive the tdo_en function. The default is "tdo_en". This property is only used when the HostScanInterface is for a TAP scan interface and the tdo port is not driven by an output pad buffer in which case no tdo_en port is created as the tdo_en signal is connected to the enable pin of the output pad buffer.

- tdo_en_polarity : active_high | active_low | auto;

  This property defines the polarity of the port or the pin name that receive the tdo_en function. This property is only used when the HostScanInterface is for a TAP scan interface. If the tdo port is driven by an output pad buffer, the tdo_en_polarity is inferred from the polarity of the enable on the TAP. An error is generated if the tdo_en_polarity property is specified to active_high and the enable pin if the output buffer is active_low and vice versa. No error is ever generated if specified to auto. If the tdo port is not driven by an output pad buffer, a tdo_en port is created with the specified active polarity. The polarity active_low is used if the property is specified or defaults to auto.

- daisy_chain_with_existing_client : on | off;

  A property of type Boolean. The default is off. When set to off, the source of the scan_out pin is first disconnected before hooking up the scan-out port of the network to it. When set to on, it is assumed a valid scan-out source is already connected to the specified scan-out port. The source is used as the scan-in of the newly inserted IJTAG network. Example 1 illustrates this.

Example 1

The following example has three HostScanInterface wrappers. The first wrapper called purple is used to insert a SIB called red in series with whatever is already connected to the purple HostScanInterface (the gray SIB in Figure 5-3). The second wrapper, called pink, is used to connect a SIB called orange to the Host ScanInterface of an existing instance in the design which, in this example, is a SIB inserted in an initial insertion pass. The third wrapper, called gray, is used to connect a SIB called green in series with the Client ScanInterface of an existing instance in the design which, in this example, is a SIB inserted in an initial insertion pass.

```
DftSpecification(design1,pass2) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Interface {
        scan_in    : si;
        scan_out   : so;
        capture_en : ce;
        shift_en   : se;
        update_en  : ue;
        reset      : rstn;
        select     : sel;
        daisy_chain_with_existing_client : on;
      }
      Sib(red) {
      }
    }
    HostScanInterface(pink) {
      Interface {
```

```
          scan_in     : si;
          scan_out    : tessent_pass1_sib_first_inst/ijtag_from_so;
          capture_en  : ce;
          shift_en    : se;
          update_en   : ue;
          reset       : rstn;
          select      : tessent_pass1_sib_first_inst/ijtag_to_sel;
        }
        Sib(orange) {
        }
      }
      HostScanInterface (gray){
        Interface {
          design_instance   : tessent_pass1_sib_first_inst;
          scan_interface    : client;
        }
        Sib(green) {
        }
      }
    }
  }
```

Figure 5-3. HostScanInterface/Interface Example Schematic

Example 2

The next example shows how to connect a SIB to the TAP controller inserted by ETAssemble as part of one of the LV flows. The first DftSpecification wrapper uses the design_instance syntax. The second DftSpecification wrapper uses explicit function connections but results in the same implementation as the first one. Although the second method is more verbose, it works even when the connections are not all made to a single instance having an associated ICL module, which is a requirement for the first method.

```
DftSpecification(my_design,post_etassemble) {
  IJTAGNetwork {
    HostScanInterface(ijtag){
      Interface {
        design_instance : LVISION_JTAP_INST;
        scan_interface  : Bist4;
      }
      Sib(1) {
      }
    }
  }
}

DftSpecification(my_design,post_etassemble) {
  IJTAGNetwork {
    HostScanInterface(ijtag){
      Interface {
        scan_in        : LVISION_JTAP_INST/tdi;
        scan_out       : LVISION_JTAP_INST/fromBist4;
        select         : LVISION_JTAP_INST/bistEn4;
        capture_en     : LVISION_JTAP_INST/captureDR2Edge;
        shift_en       : LVISION_JTAP_INST/shiftDR2Edge;
        update_en      : LVISION_JTAP_INST/updateDREnable;
        reset          : LVISION_JTAP_INST/testLogicResetInv;
        reset_polarity : active_low;
        tck            : LVISION_JTAP_INST/tck;
        }
        Sib(1) {
        }
      }
    }
  }
```

IjtagNetwork/DataInPorts

Syntax

```
IjtagNetwork {
  DataInPorts {
    count              : integer;           // default: auto
    port_naming        : port_naming, ...;  // default: ijtag_data_in[%d]
    multiplexing       : on | off | auto;
    connection(range)  : pin_name;          // repeatable
  }
}
```

Description

A wrapper that specifies data-in ports that may or may not exist as input ports on the current design.

These data-in ports can be used to source data-in ports on child design instances, or to source the select port of a ScanMux as shown in the example for this wrapper.

Parameters

- count : *integer*;

  A property to request a specific number of data-in ports. By default, the count is determined to be large enough to satisfy the *range* value of all connection properties.

- port_naming : *port_naming, ...;*

  A property that specifies the naming of the data-in ports. The port_naming value has two distinct formats: a single string using an index symbol “%d”, or a list of port names with explicit sizes.

  When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Din%2d will create Din00, Din01, Din02, and so on. Din%d and Din%1d mean the same thing. The default is “ijtag_data_in[%d]”.

  When using a list of port names, you control the exact naming and width of each data-in port. For example, if you specify “locked”, you will get exactly one data-in port called “locked” as illustrated in Example 2 of the Tdr/DataInPorts section.

- multiplexing : on | off | auto;

  A property that specifies if a multiplexer is to be added when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-in port is added to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See Example 2 in the Tdr/DataOutPorts section for an illustration of this.

- connection*(range) : pin_name;*

  A repeatable property that specifies the connections to make between the bits of the data-in ports and the existing pins inside the design. Because data-in ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.

  If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the process_dft_specification -no_insertion option is not used. If you are using the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Example

The following example illustrates defining five data-in ports. The ports are named my_data_in04, my_data_in03, my_data_in02, my_data_in01, and my_data_in00. The port my_data_in00 is connected to the “en” pin of the u2/top_green instance. The ports my_data_in03, my_data_in02, and my_data_in01 are connected to the mode[2:0] pins of the same instance. If the count property was not specified, it would have defaulted to four, corresponding to the largest specified connection range index value of three. In this example, a count of five is specified to request an extra data-in port to be used by the select port of the ScanMux(red) used in the HostScanInterface(purple).

Notice that if this core was further integrated into a parent design and a Tdr was used to source the five data-in ports, the property output_timing(4) with a value of “ijtag_scan_selection” would need to be specified because bit 4 is used to reconfigure the scan network. For further explanation, see section “Update Stage Timing.”

The tool is currently unable to determine if the data-in port on a design instance is used to reconfigure the network within the specified design instance but this automation is planned for the future.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    DataInPorts {
      Count           : 5;
      port_naming     : my_data_in%2d;
      connection(0)   : u2/top_green/en;
      connection(3:1) : u2/top_green/mode[2:0];
    }
    DataOutPorts {
      port_naming : my_data_out[%d];
      connection(0) : u2/top_green/go;
      connection(1) : u2/top_green/done;
    }
    HostScanInterface(purple) {
      ScanMux(red) {
        select : DataIn(4);
        Input(1) {
          DesignInstance (u1/bottom_green) {}
        }
      }
    }
  }
```

```
}
```

IjtagNetwork/DataOutPorts

Syntax

```
IjtagNetwork {
  DataOutPorts {
    count              : integer;          // default: auto
    port_naming        : port_naming, ...; // default: ijtag_data_out[%d]
    Connection(range)  : pin_name;         // repeatable
  }
}
```

Description

A wrapper that specifies data-out ports that may or may not exist as output ports on the current design.

These data-out ports can be used to observe data-out ports on child design instances.

Parameters

- count : *integer*;

  A property to request a specific number of data-out ports. By default, the count is determined to be large enough to satisfy the largest range value of the connection properties.

- port_naming : *port_naming, ...;*

  A property that specifies the naming of the data-out ports. The port_naming value as two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

  When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Dout%2d will create Dout00, Dout01, Dout02, and so on. Dout%d and Dout%1d mean the same thing. The default is “ijtag_data_out[%d]”.

  When using a list of port names, you control the exact naming and width of all data-out ports. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly seven data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in Example 2 of the Tdr/DataOutPorts section.

- connection*(range)* : *pin_name;*

  A repeatable property that specifies the connections to make between the bits of the data-out port and the existing pins inside the design. Because data-out ports are sinks, the same bit cannot be connected to multiple sources. It is, therefore, illegal to repeat the connection property with overlapping range indexes.

  If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the process_dft_specification -no_insertion option is not used. If you are using the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Example

The following example illustrates the creation of two data-out ports. The count property is not specified so it defaults to two corresponding to the largest connection *range* index used. The port naming is specified to define a port named “my_data_out[1:0]”. Each bit is connected to a unique source.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    DataOutPorts {
      port_naming : my_data_out[%d];
      connection(0) : u2/top_green/go;
      connection(1) : u2/top_green/done;
    }
  }
}
```

      }
    }
  }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a scan multiplexer into the design. The Input(0) and Input(1) wrappers are used to defined the nodes that feed into that input of the multiplexer. If you omit an Input wrapper, the multiplexer simply bypasses the elements connected to the other input when the unspecified input is selected. See the example that follows for an illustration of this feature.

The actual schematic of the multiplexer is shown in Figure 5-5 and Figure 5-6. As you can see, the scan multiplexer is actually more than a simple multiplexer. When used in a DR scan path, it also has logic to supply a select line (output_en1 and output_en0) for each set of clients connected to the two scan inputs (input1 and input0). When used in a TAP scan path, it also has logic to supply a to_tms (to_tms1 and to_tms0) for each set of tap clients connected to the two scan inputs (input1 and input0).The output port is the multiplexed scan-out data of the clients to source the scan-in of the host or of the next node in series with the ScanMux.

The select input is sourced by a data signal which is either one of the DataInPorts of the IjtagNetwork, one of the DataOutPorts of a Tdr or a Tap, or an output port on an existing design instance. The select input is used to control the multiplexer and to create two gated versions of the enable_in or tms inputs. The gated versions are used as the select or tms source of the clients connected to each scan input. The enable_in port is sourced by the host of the ScanMux. If the host is a Sib, the enable_in is sourced by the to_select port. If the host is another ScanMux, the

enable_in port is sourced by one of the “enable_out#” ports. If the host is the HostScanInterface, the enable_in is sourced by the select port. The tms port is sourced by the host of the ScanMux. If the host is a ScanMux, the tms port is sourced by one of the “to_tms#” ports. If the host is the HostScanInterface, the tms is sourced by the tms port.

When the reuse_modules_when_possible property is set or inferred to be on in the DftSpecification wrapper, the ScanMux module names are hardcoded to <design_name>_<design_id>_tessent_scanmux_# where # is an integer incrementing from 1. A unique module is created for each combination of port names in the interface wrapper, attributes in the Attributes wrapper, and the value of the keep_active_during_scan_test property.

When the reuse_modules_when_possible property is set or inferred to be off in the DftSpecification wrapper, the ScanMux module names are hardcoded to <design_name>_<design_id>_tessent_scanmux_<id>.

Figure 5-5. ScanMux Internal Schematic When Used on a DR Scan Path

Figure 5-6. ScanMux Internal Schematic When Used on a TAP Scan Path

Parameters

- *id*

  A unique id that contains only letters, numbers, and underscores. Every ScanMux wrapper must have a different *id* inside a common IjtagNetwork wrapper.

- parent_instance : *instance_name;*

  A string property that specifies the parent instance in which to instantiate the scan mux module. If this property is not unspecified, the scan mux is instantiated in the root module. You can use this property to push a scan multiplexer down near the client interfaces it interacts with.

  If the specified instance_name is an instance of a repeated module, a warning is displayed during validation and a uniquify_instances command is automatically issued as part of the insertion process to uniquify the instance_name.

  To perform IJTAG network insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a single Tessent Shell invocation. You simply change the current design using the set_current_design command in setup mode.

- leaf_instance_name : *leaf_instance_name*;

  A string property that specifies the leaf instance name of the scan multiplexer. The property defaults to "<design_name>_<dft_spec_id>_tessent_scanmux_<scanmux_id>_inst" when unspecified. The *dft_spec_id* string is the *id* specified in the DftSpecification wrapper, and the *scanmux_id* is the *id* of the ScanMux wrapper. Tessent Shell checks for conflicts before instantiating the scan multiplexer and, if needed, applies the uniquification suffix specified by the set_insertion_options command.

- select : *source*;

  A string property that specifies the source of the select. The source must match one of the formats described in this table.

Format	**Description**
DataIn(*integer*)	Specifies that the source of the select is one of the DataInPorts of the IjtagNetwork wrapper. The *integer* value must be between *count* -1 and 0 where *count* is a property that specifies the number of DataInPorts.
Tdr(*id*)/DataOut(*integer*)	Specifies that the source of the select is one of the DataOutPorts of a Tdr. The *integer* value must be between *count* -1 and 0 where *count* is a property that specifies the number of DataOutPorts on the Tdr(*id*).
Tdr(*id*)/DecodeSignal(*name*)	Specifies that the source of the select is one of the DecodedSignal of a Tdr. The *name* value must be the name of a decoded signal on the Tdr(*id*).
Tap(*id*)/DataOut(*integer*)	Specifies that the source of the select is one of the DataOutPorts of a Tap. The *integer* value must be between *count* -1 and 0 where *count* is a property that specifies the number of DataOutPorts on the Tap(*id*).
DesignInstance(*inst_name*)/*port_name*	Specifies that the source of the select is a port on the module with the instance name *inst_name*. During ICL extraction, this pin must be or must trace to a DataOutPort or a ToSelect port of an ICL module.

- Attributes/*attribute_name* : *attribute_value*;

  A data wrapper that defines arbitrary attributes in the ScanMux ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using get_attribute_value_list, you must have registered the attribute using the "register_attribute -object_type icl_module" command. For example, assuming you have

registered the attribute att1 on the icl_module object type, and you have added the attribute att1 with a value of "v1" in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the "get_icl_modules -filter att1==v1" command.

- Input(0|1)/keep_active_during_scan_test : on | off | auto;

  A property that specifies that all clients connected to the ScanMux input are to be kept active during scan test modes. You should rarely need to use this property because when it is auto (default), it is automatically set to on if a Tdr with keep_active_during_scan_test set to on traces to it. See section "Scan Testability of the IJTAG Network" on page 117 for information about when to use this property.

Example

The following example illustrates the use of scan multiplexers in the DR scan paths of the IJTAG network. See Figure 5-13 for an example use in the TAP scan path. The red mux has client nodes specified in both of its Input wrappers which make it a selection multiplexer. The pink mux only has client nodes in its "1" Input wrapper making it a bypass multiplexer. The clients connected to the "1" input are bypassed when the select is low. For both multiplexers, a data-out bit on the black TDR is used as the source of the select signal.

The AND gates shown at the bottom of Figure 5-7 illustrate the distributed gating mechanism used to generate the select signals for the multiplexed TDRs. These AND gates correspond to the AND gates shown in Figure 5-5.

```

        enable_out0  : port_name; // default: enable_out0
        enable_out1  : port_name; // default: enable_out1

        tms          : port_name; // default: tms
        to_tms0      : port_name; // default: to_tms0
        to_tms1      : port_name; // default: to_tms1
        tdo_en       : port_name; // default: tdo_en
        from_tdo_en0 : port_name; // default: from_tdo_en0
        from_tdo_en1 : port_name; // default: from_tdo_en1
      }
    }
  }
}
```

Description

A wrapper that specifies the name of the ports when creating the ScanMux module.

All port names can be specified by the user; however, they can only be simple scalar port names.

Parameters

- select : *port_name;*

  This property defines the name of the port labelled “select” in Figure 5-5 and Figure 5-6. The default is “mux_select”.

- input0 : *port_name;*

  This property defines the name of the port labelled “input0” in Figure 5-5 and Figure 5-6. The default is “mux_in0”.

- input1 : *port_name;*

  This property defines the name of the port labelled “input1” in Figure 5-5 and Figure 5-6. The default is “mux_in1”.

- output : *port_name;*

  This property defines the name of the port labelled “output” in Figure 5-5 and Figure 5-6. The default is “mux_out”.

- enable_in : *port_name;*

  This property defines the name of the port labelled “enable_in” in Figure 5-5. The default is “enable_in”.

- enable_out0 : *port_name;*

  This property defines the name of the port labelled “enable_out0” in Figure 5-5 and Figure 5-6. The default is “enable_out0”.

- enable_out1 : *port_name;*

  This property defines the name of the port labelled “enable_out1” in Figure 5-5. The default is “enable_out1”.

- tms : *port_name;*

  This property defines the name of the port labelled “tms” in Figure 5-6. The default is “tms”.

- to_tms0 : *port_name;*

  This property defines the name of the port labelled “to_tms0” in Figure 5-6. The default is “to_tms0”.

- to_tms1 : *port_name;*

  This property defines the name of the port labelled “to_tms1” in Figure 5-6. The default is “to_tms1”.

- tdo_en : *port_name;*

  This property defines the name of the port labelled “tdo_en” in Figure 5-6. The default is “tdo_en”.

- from_tdo_en0 : *port_name;*

  This property defines the name of the port labelled “from_tdo_en0” in Figure 5-6. The default is “from_tdo_en0”.

- from_tdo_en1 : *port_name;*

  This property defines the name of the port labelled “from_tdo_en1” in Figure 5-6. The default is “from_tdo_en1”.

Example

The following example illustrates the use of this wrapper to specify custom port names for the scan multiplexer used in a DR Scan Path.

```
IjtagNetwork {
   HostScanInterface(id) {
      ScanMux(id) {
         Interface {
            select      : sm_select;
            input0      : sm_si0;
            input1      : sm_si1;
            output      : sm_so;
            enable_in   : sm_en;
```

```
                enable_out0 : sm_en0;
                enable_out1 : sm_en1;
            }
        }
    }
}
```

```

Description

A wrapper that specifies the creation and, optionally, the insertion of a SIB (Scan Inclusion Bit) into the IJTAG network.

A SIB is a special node in IJTAG that contains a single bit shift register. When the bit is zero, the SIB bypasses the client nodes connected to its host port. When the bit is one, the SIB includes the client nodes connected to its host port as part of the active scan path. Figure 5-8 shows the detailed schematic of its implementation.

The shift register value is latched into the update stage on the falling edge of TCK when update_en is active. A delay stage is then used to delay the transition of to_select_en by one TCK cycle so as to avoid timing races that will exist if TCK is not perfectly balanced between the SIB and its clients. Refer to section "Update Stage Timing" for more details about this feature.

When the reuse_modules_when_possible property is set or inferred to be on in the DftSpecification wrapper, the SIB module names are hardcoded to <design_name>_<design_id>_tessent_sib_# where # is an integer incrementing from 1. A unique module is created for each combination of port names in the interface wrapper, attributes in the Attributes wrapper, and the value of the capture_value and keep_active_during_scan_test properties.

When the reuse_modules_when_possible property is set or inferred to be off in the DftSpecification wrapper, the SIB module names are hardcoded to <design_name>_<design_id>_tessent_sib_<id>.

Figure 5-8. SIB Internal Schematic

As described in the create_dft_specification command description, the instruments that need to remain active during scan are inserted under one SIB, and the ones which are scan tested, such as a memory BIST controller, are inserted under another SIB, This SIB is identified with a tessent_dft_function attribute set to “scan_tested_instrument_host”. When this attribute is defined as such, the SIB is equiped with the added logic shown in Figure 5-9 such that the IJTAG network which is scan tested is fully exercised by the scan test.

Figure 5-9. Added Scan Isolation Logic for SIB(sti)

Parameters

- *id*

  A unique id that contains only letters, numbers, and underscores. Every Sib wrapper must have a different id value inside the IjtagNetwork wrapper.

- parent_instance : *instance_name*;

  A string property that specifies the parent instance in which to instantiate the SIB module. If unspecified, the SIB is instantiated in the root module. You can use this property to push a SIB down near the client interfaces it interacts with.

  If the specified instance_name is an instance of a repeated module, a warning is displayed during validation and a uniquify_instances command is automatically issued as part of the insertion process to uniquify the instance_name.

  To perform IJTAG network insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a

single Tessent Shell invocation. You simply change the current design using the set_current_design command in setup mode.

- leaf_instance_name : *leaf_instance_name*;

  A string property that specifies the leaf instance name of the SIB. It defaults to "<design_name>_<dft_spec_id>_tessent_sib_<sib_id>_inst" when unspecified. The *dft_spec_id* string is the *id* specified in the DftSpecification wrapper, and the *sib_id* is the *id* of the SIB. Tessent Shell checks for conflicts before instantiating the SIB and, if needed, applies the uniquification suffix specified by the set_insertion_options command.

- keep_active_during_scan_test : on | off | auto;

  A property that specifies that all nodes serially connected to the SIB are to be kept active during scan test modes. For information about when to use this property, see the section "Scan Testability of the IJTAG Network" on page 117.

- capture_value : 0 |1 | self;

  The property controls what the shift register captures during the capture cycle. By default it captures a constant 0 which provides a predictable value that can always be compared when it comes out on the scan-out pin. Specifying "self" makes the SIB hold during capture. The multiplexer closest to the shift stage in Figure 5-8 is simply removed when using the "self" value. For the diagnostic hold time issue in the scan path, it is recommended to keep the default capture value of 0.

- Attributes/*attribute_name* : *attribute_value*;

  A data wrapper that defines arbitrary attributes in the SIB ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using get_attribute_value_list, you must have registered the attribute using the "register_attribute -object_type icl_module" command. For example, assuming you have registered the att1 attribute on the icl_module object type, and you have added the att1 attribute with a value of "v1" in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the "get_icl_modules -filter att1==v1" command.

Example

The following example illustrates the use of SIBs to provide discrete access to multiple parts of a complex network. There are three SIBs at the top of the network. The first SIB, which is closest to the scan-out and has an id value of "logictest_hw", is used to provide access to a TDR that is used to create the scan mode enable signals. Because the TDR id has a value of "scan_modes", the property keep_active_during_scan_test defaults to on, which in turns propagates to the three SIBs at the top of the network.

The second SIB, with an *id* value of "scanable_instruments", is used to access all instruments that will not be kept active during scan test but, instead, will be scan tested like the rest of the normal functional logic. This SIB can remain closed during the scan test modes such that the rest of the network remains stable and provides valid and undisturbed test_setup values.

The third SIB. with an *id* value of “child_cores”, is used to access a chain of SIBs. The chained SIBs independently open the scan path to each child core. The presence of these SIBs guarantees that a defective core or a powered down core can always be bypassed when accessing other cores.

```
DftSpecification(top,setup_hw) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(logictest_hw) {
        Tdr(scan_modes) {
          DecodedSignal(edt) {
            decode_values : 2'b01, 2'b10;
          }
          DecodedSignal(edt_config2) {
            decode_values : 2'b10;
          }
          DecodedSignal(multi_bypass) {
            decode_values : 2'b11;
          }
          DecodedSignal(scan_test_en) {
            decode_values : 2'b01, 2'b10, 2'b11;
          }
        }
      }
      // Everything below this Sib is scan tested.
      // This sibs remains off when setting up logictest_hw
      sib(scanable_instruments) {
        sib(mbist1) {
        }
        sib(mbist2) {
        }
      }
      sib(child_cores) {
        sib(c1) {
          DesignInstance(corea_i1) {
          }
        }
        sib(c2) {
          DesignInstance(corea_i2) {
          }
        }
        sib(c3) {
          DesignInstance(coreb_i1) {
          }
        }
      }
    }
  }
}

            }
         }
      }
   }
}
```

Description

A wrapper that contains a Client and Host wrapper that together fully specify the client and host ports.

The Client wrapper provides properties to fully specify the names of the eight client ports, and also contains a property to define the reset polarity of the reset port. The Host wrapper provides properties to fully specify the names of the two host ports.

Parameters

- Client/select : *port_name*;

  This property defines the name of the port labelled “ijtag_sel” in Figure 5-8. The default is “ijtag_sel”.

- Client/tck: *port_name*;

  This property defines the name of the port labelled “ijtag_tck” in Figure 5-8. The default is “ijtag_tck”.

- Client/scan_in : *port_name*;

  This property defines the name of the port labelled “ijtag_si” in Figure 5-8. The default is “ijtag_si”.

- Client/scan_out : *port_name*;

  This property defines the name of the port labelled “ijtag_so” in Figure 5-8. The default is “ijtag_so”.

- Client/reset : *port_name*;

  This property defines the name of the port labelled “ijtag_reset” in Figure 5-8. The default is “ijtag_reset”.

- Client/reset_polarity : active_low | active_high;

  This property defines the active polarity of the port labelled “ijtag_reset” in Figure 5-8. The default is “active_low”.

- Client/shift_en : *port_name*;

  This property defines the name of the port labelled “ijtag_se” in Figure 5-8. The default is “ijtag_se”.

- Client/capture_en : *port_name*;

  This property defines the name of the port labelled “ijtag_ce” in Figure 5-8. The default is “ijtag_ce”.

- Client/update_en : *port_name*;

  This property defines the name of the port labelled “ijtag_ue” in Figure 5-8. The default is “ijtag_ue”.

- Host/to_select : *port_name*;

  This property defines the name of the port labelled “ijtag_to_sel” in Figure 5-8. The default is “ijtag_to_sel”.

- Host/scan_in : *port_name*;

  This property defines the name of the port labelled “ijtag_from_so” in Figure 5-8. The default is “ijtag_from_so”.

Example

The following example illustrates fully specifying a unique name for each port.

```
IjtagNetwork {
   HostScanInterface (id) {
      Sib(id) {
         Interface {
            Client {
               select          : sel;
               tck             : tck;
               scan_in         : si;
               scan_out        : so;
               reset           : reset;
               shift_en        : se;
               capture_en      : ce;
               update_en       : ue;
            }
            Host {
```

```
                    to_select       : to_sel;
                    scan_in         : from_so;
                }
            }
        }
    }
}
```

}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a TAP controller into the IjtagNetwork.

A TAP is a special node in IJTAG. It contains an IEEE1149.1 state machine controlled by a TMS port. The TMS port is used to steer the state machine into various states and control when the capture, shift, and update cycles happen. Unlike a SIB and a TDR, which are only active in the DR States, the TAP has an instruction register that is activated in the IR States. The value in the instruction register determines which data register is selected when in the DR States. The TAP state machine is illustrated in Figure 5-11. A block diagram of a TAP controller is shown in Figure 5-12.

A TAP wrapper is only allowed to exist in a HostScanInterface or inside the Input wrapper of a ScanMux. A TAP is only allowed to be in series with other TAP controllers and can never be in series with Tdr and Sib nodes even through ScanMux nodes. The name of all ports on the TAP controller are user-specifiable using the Interface wrappers. BoundaryScan host ports are present when the HostBscan wrapper is specified. The device id register is present when the DeviceIDRegister wrapper is specified. Finally, the IJTAG host ports are present when one or more HostIjtag wrappers are specified. The bypass register is required and always present.

If you are familiar with the LogicVision TAP, you will remember that it had an internal DR register used to observe status bits and control user bits and decoded signals. If you need such a register, you can and should use a Tdr wrapper inside a HostIjtag wrapper of the Tap; this will give you access to the Tdr/DataInPorts, Tdr/DataOutPorts, and Tdr/DecodedSignal wrapper syntax.

All registers operate on the rising edge of TCK except for the update stage, labelled “inst_latch” in Figure 5-12 on page 154, which operates on the falling edge of TCK.

The tap module names are hardcoded to <design_name>_<design_id>_tessent_tap_<id>.

Figure 5-11. TAP FMS Diagram

Figure 5-12. TAP Block Diagram

Parameters

- *id*

  A unique id that contains only letters, numbers, and underscores. Every Tap wrapper must have a different id value inside the IjtagNetwork wrapper.

- parent_instance : *instance_name*;

  A string property that specifies the parent instance in which to instantiate the TAP module. If unspecified, the TAP is instantiated in the root module. You can use this property to push a TAP down near the client interfaces it interacts with.

  If the specified instance_name is an instance of a repeated module, the tool issues a warning during validation and automatically issues a uniquify_instances command as part of the insertion process to uniquify the instance_name.

  To perform IJTAG network insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IITAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a

single Tessent Shell invocation. You simply change the current design using the set_current_design command in setup mode.

- leaf_instance_name : *leaf_instance_name*;

  A string property that specifies the leaf instance name of the TAP. It defaults to "<design_name>_<dft_spec_id>_tessent_tap_<tap_id>_inst" when unspecified. The dft_spec_id string is the id specified in the DftSpecification wrapper, and the tap_id is the id of the Tap wrapper. Tessent Shell checks for conflicts before instantiating the TAP controller and, if needed, applies the uniquification suffix specified by the set_insertion_options command.

- keep_active_during_scan_test : on | off | auto;

  A property that specifies that all nodes serially connected to the TAP are to be kept active during scan test modes. For information about when to use this property, see the section "Scan Testability of the IJTAG Network" on page 117.

- bypass_instruction_codes : auto | binary, ... ;

  A property used to define one or many opcodes for the BYPASS instruction. The all 0 code is automatically assigned to the BYPASS instruction whether specified or not. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- Attributes/*attribute_name* : *attribute_value*;

  A data wrapper that defines arbitrary attributes in the TAP ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL at a later time. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using get_attribute_value_list, you must have registered the attribute using the "register_attribute -object_type icl_module" command. For example, assuming you have registered the att1 attribute on the icl_module object type, and you have added the att1 attribute with a value of "v1" in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the "get_icl_modules -filter att1==v1" command.

Example

This example defines two TAP controllers where a DataOutPort on the primary TAP is used to control if the secondary TAP is active or not. When the DataOutPort on the primary TAP is high, the secondary TAP is in series with it. When the DataOutPort on the primary TAP is low, the secondary TAP is bypassed and it is held in run_test_idle by gating its tms port low.

```
DftSpecification(module_name,id) {
  IjtagNetwork {
    HostScanInterface(purple) {
      ScanMux(green) {
        select : Tap(main)/DataOut(0);
        Input(1) {
          Tap(secondary) {
            HostIjtag(0) {
```

```
                Tdr(pink) {
                }
              }
            }
          }
        }
        Tap(main) {
          DataOutPorts {
            count : 1;
          }
        }
      }
    }
  }

    }
  }
}
```

Description

A wrapper that contains a Client and Host wrapper that together fully specify the names and polarity of the client and host ports.

The Client wrapper provides properties to fully specify the names of the six client ports, and also contains a property to define the polarity of the tdo_en port. The Host wrapper provides properties to fully specify the names of the four global host ports as well as a property to define the polarity of the reset port. The rest of the host ports related to the IJTAG and boundary scan ports are specified in the Tap/HostIjtag and Tap/HostBScan wrappers respectively.

Parameters

- fsm_state : port_name;

  This property defines the name of the port labelled “fsm_state” in Figure 5-12. The specified value must end with “[%d]”. The default is “fsm_state[%d]”.

- Client/tdi : port_name;

  This property defines the name of the port labelled “tdi” in Figure 5-12. The default name when unspecified is “tdi”.

- Client/tdo : port_name;

  This property defines the name of the port labelled “tdo” in Figure 5-12. The default name when unspecified is “tdo”.

- Client/tck : port_name;

  This property defines the name of the port labelled “tck” in Figure 5-12. The default name when unspecified is “tck”.

- Client/tms : port_name;

  This property defines the name of the port labelled “tms” in Figure 5-12. The default name when unspecified is “tms”.

- Client/trst : port_name;

  This property defines the name of the port labelled “trst” in Figure 5-12. The default name when unspecified is “trst”. This port is always active low.

- Client/tdo_en : port_name;

  This property defines the name of the port labelled “tdo_en” in Figure 5-12. The default name when unspecified is “tdo_en”. Its active polarity is controlled by the tdo_en _polarity property. The port is active in the Shift-DR and Shift-IR states. See Figure 5-11 for a diagram of the state machines.

- Client/tdo_en_polarity : active_high | active_low;

  This property controls the polarity of the tdo_en port. The default is active_low. When the DftSpecification is created by the create_dft_specification command, the property is automatically specified to match the polarity of the enable pin for the output pad buffer associated to the tdo port.

- Host/reset : port_name;

  This property defines the name of the port labelled “reset” in Figure 5-12. The default name when unspecified is “test_logic_reset”. Its active polarity is defined using the reset_polarity property. This port is active when the TAP fsm is in the TestLogicReset state which can be synchronously entered by keeping the tms port high for a minimum of 5 TCK cycles or asynchronously entered by setting the trst port to zero.

- Host/capture_en : port_name;

  This property defines the name of the port labelled “capture_en” in Figure 5-12. The default name when unspecified is “capture_dr_en”.

- Host/shift_en : port_name;

  This property defines the name of the port labelled “shift_en” in Figure 5-12. The default name when unspecified is “shift_dr_en”.

- Host/update_en : port_name;

  This property defines the name of the port labelled “update_en” in Figure 5-12. The default name when unspecified is “update_dr_en”.

- Host/reset_polarity : active_high | active_low;

  This property defines the active polarity of the reset port.

Example

This example defines all client ports with a “client_” prefix and all host ports with a “host_” prefix. The polarity of tdo_en and reset are both specified as active high.

```
DftSpecification(module_name,id) {

Tap/DataOutPorts

Syntax

```
DftSpecification(module_name,id) {

  IjtagNetwork {
    HostScanInterface(id) {
      Tap(id) {
        DataOutPorts {
          count       : int | auto;
          port_naming : port_name, ... ; // default: user_ir_bits[%d]
          multiplexing : on | off | auto;
          connection(range) : pin_name ; // repeatable
        }
      }
    }
  }
}
```

Description

A wrapper that specifies the number (count) of data-out ports to create on the TAP module, the naming of the ports, the connections to make from them, and whether multiplexing is to be inserted when making the connections.

We do not recommend using the TAP as a source of DataOut ports. Instead, you should use the Tdr/DataOutPorts wrapper as a source. It is good practice to include a data-out port on a TAP to control the select of a ScanMux that inserts one or many secondary TAP controllers in series with the main one as illustrated in Figure 5-13. Notice that the property output_timing which exists in the Tdr/DataOutPorts wrapper is not present. There is no risk of races here because the TAP data-out ports change in the Update-IR state while all client registers are only reacting to the Update-DR state. When using the data-out port to control the insertion or exclusion of a TAP controller, the TMS signal is clocked on the rising edge of TCK, and the data-out signal changes on the falling edge of TCK thereby removing any risk of races.

Parameters

- count : *integer*;

  A property that specifies the number of data-out bits needed on the TAP. By default, the count is determined to be large enough to satisfy the range value of all connection properties.

- port_naming : *port_naming*;

  A property that specifies the naming of the data-out ports. The port_naming value has two distinct formats: a single string using an index symbol, or a list of port names with explicit sizes.

  When using the indexed format, you specify “base_name[%d]” when you want to use a bus and you specify “base_name%<integer>d” when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the

integer is padded with 0s to be at least <integer> bits wide. For example, “Dout%2d” will create Dout00, Dout01, Dout02, and so on. “Dout%d” and “Dout%1d” mean the same thing. The default is “user_ir_bits[%d]”.

When using a list of port names, you control the exact naming and width of each data-out port. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly 7 data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in Example 2 of the Tdr/DataOutPorts.

- multiplexing : `on | off | auto;`

  A property that specifies whether to add a multiplexer when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See this illustrated in Example 2 of the Tdr/DataOutPorts wrapper.

- connection`(range)` : `pin_name`;

  A repeatable property that specifies connections to make between bits of the data-out ports and existing pins inside the design. Because data-out ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.

  If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the “process_dft_specification -no_insertion” option is not used. If you are using the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Example 1

The “Example” on page 155 illustrates the creation of a data-out port with no connection property. The connection to the data-out port is done using the select property of the ScanMux as illustrated in Figure 5-13.

Example 2

The following example illustrates the specification of four data-out ports with connections to pins on a design instance.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Tap(orange) {
        DataOutPorts {
          connection(0)    : u2/top_green/en;
          connection(3:1) : u2/top_green/mode[2:0];
        }
      }
    }
  }
}
```

Tap/DeviceIDRegister

Syntax

```
DftSpecification(module_name,id) {

  IjtagNetwork {
    HostScanInterface(id) {
      Tap(id) {
        DeviceIDRegister {
          Interface {
            version_code       : port_name; //def: version_code[%d]
            part_number_code   : port_name; //def: part_number_code[%d]
          }
          capture_source       : internal | external;

          instruction_codes    : auto | binary, ... ;

          version_code         : binary; // default: 4'h0
          manufacturer_id_code : binary; // default: 11'h0
          part_number_code     : binary; // default: 16'h0
        }
      }
    }
  }
}
```

Description

A wrapper that specifies that the TAP controller is to be equipped with a device id register.

Properties are used to specify the version id, manufacturer id, and the part number codes. When the property capture_source is set to external, the version and part_number codes are captured from ports on the TAP controller. The port names are user-specifiable using the Interface wrapper. The specified version and part_number codes are used as tie values on the version and part_number code ports when instantiating the TAP controller inside the design.

The tool automatically assigns the instruction codes when you specify auto for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Parameters

- Interface/version_code : *port_name*;

  This property defines the name of the port labelled “version_code” in Figure 5-12. The specified value must include the “[%d]” or “%<integer>d” symbol. The default is “version_code[%d]”.

- Interface/part_number_code : port_name;

  This property defines the name of the port labelled “part_number_code” in Figure 5-12. The specified value must include the “[%d]” or “%<integer>d” symbol. The default is “part_number_code[%d]”.

- capture_source : internal | external;

  A property that defines where the capture value of the part number and version codes comes from. When the property is set to external, the version_code and part_number_code properties are captured from ports on the TAP controller. The version_code and part_number_code properties are used as tie values on the version and part_number ports when instantiating the TAP controller inside the design. When the property is set to internal, no ports are created and the capture value is describes in the RTL description of the TAP. The default value is external.

- instruction_codes : auto | binary, ... ;

  A property used to define one or many opcodes for the DEVICE_ID instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- version_code : binary;

  A property that specifies a version id code using a 4-bit binary or hexadecimal number. The default value is “4'h0”.

- manufacturer_id_code : binary;

  A property that specifies a manufacturer id code using an 11-bit binary or hexadecimal number. The default value is “11'h0”.

- part_number_code : binary;

  A property that specifies a part number code using a 16-bit binary or hexadecimal number. The default value is “16'h0”.

Example

This example specifies that the TAP controller is to have a device id register. The version and part number codes are encoded as tie values on ports of the TAP controller.

```
DftSpecification (module_name,id) {

  IjtagNetwork {
    HostScanInterface(id) {
      Tap(id) {
        DeviceIDRegister {
          version_code      : 4'h0;
          manufacturer_id_code : 11'hA3;
          part_number_code     : 16'h0105;
        }
      }
    }
  }
}

            HIGHZ              : auto | unused | binary, ... ;
          }
        }
      }
    }
  }
}
```

Description

The presence of this wrapper specifies that the TAP is to be equipped with a port capable of hosting a boundary scan chain.

The interface wrapper is used to change the default port naming of the various functions.

The tool automatically assigns the instruction codes when you specify auto for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Parameters

- Interface/select : *port_name*;

  This property defines the name of the port labelled “bscan_select” in Figure 5-12. The default is “host_bscan_to_sel”.

- Interface/force_disable : *port_name*;

  This property defines the name of the port labelled “force_disable” in Figure 5-12. The default is “force_disable”.

- Interface/select_jtag_input : *port_name*;

  This property defines the name of the port labelled “select_jtag_input” in Figure 5-12. The default is “select_jtag_input”.

- Interface/select_jtag_output : *port_name*;

  This property defines the name of the port labelled “select_jtag_output” in Figure 5-12. The default is “select_jtag_output”.

- Interface/extest_pulse : *port_name*;

  This property defines the name of the port labelled “extest_pulse” in Figure 5-12. The default is “extest_pulse”. This port is not created when the EXTEST_PULSE property inside the Tap/HostIjtag wrapper is specified as “unused”.

- Interface/extest_train : *port_name*;

  This property defines the name of the port labelled “extest_train” in Figure 5-12. The default is “extest_train”. This port is not created when the EXTEST_TRAIN property inside the Tap/HostIjtag wrapper is specified as “unused”.

- Interface/scan_in : *port_name*;

  This property defines the name of the port labelled “from_bscan_so” in Figure 5-12. The default is “host_bscan_from_so”.

- InstructionCodes/CLAMP : auto | unused | binary, ... ;

  A property used to define one or many opcodes for the CLAMP instruction. All codes must differ from the other codes by at least one non-X bit. When left as auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/EXTEST : auto | binary, ... ;

  A property used to define one or many opcodes for the EXTEST instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified.

- InstructionCodes/EXTEST_PULSE : auto | unused | binary, ... ;

  A property used to define one or many opcodes for the EXTEST_PULSE instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/EXTEST_TRAIN : auto | unused | binary, ... ;

  A property used to define one or many opcodes for the EXTEST_TRAIN instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan

wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/INTEST : auto | unused | binary, ... ;

  A property used to define one or many opcodes for the INTEST instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/SAMPLE_PRELOAD : auto | binary, ... ;

  A property used to define one or many opcodes for the SAMPLE_PRELOAD instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified.

- InstructionCodes/HIGHZ : auto | unused | binary, ... ;

  A property used to define one or many opcodes for the HIGHZ instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the Tap/HostBScan wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

Example

This example specifies that the TAP is to be equipped with a boundary scan host port. The port naming is left unspecified so the default naming is used. It specifies explicit opcodes for the required instructions related to boundary scan and makes a few of the optional ones unused. Notice that the all 0 opcode is not used as it is reserved for the bypass register. This example assumes no Tap/HostIjtag and no Tap/DataOutPorts wrappers are specified as there would be no room for those opcodes.

```
DftSpecification(mychip,rtl) {
  IjtagNetwork {
    HostScanInterface(tap) {
      Tap(main) {
        bypass_instruction_codes : 2'b00;
        HostBscan {
          InstructionCodes {
            CLAMP          : unused;
            EXTEST         : 2’b01;
            EXTEST_PULSE   : unused;
            EXTEST_TRAIN   : unused;
            IDCODE         : 2’b10;
            INTEST         : unused;
            SAMPLE_PRELOAD : 2'b11;
            HIGHZ          : unused;
          }
        }
      }
    }
```

```
        }
    }
```

  }
}
```

Description

A repeatable wrapper that specifies the presence of one or many IJTAG host ports on the TAP controller.

The optional properties allow you to specify a specific opcode to access each IJTAG host port, and to name the ports. You can then specify any other IJTAG node types inside it.

The tool automatically assigns the instruction codes when you specify auto for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Parameters

- id

  A string that uniquely identifies the HostIjtag wrapper. The string contains only letters, numbers, and underscores.

- instruction_codes : auto | binary, ...;

  A property that defines one or many opcodes for the instruction that selects the IJTAG host port. All codes must differ from the other codes specified in the other wrappers such as inside the Tap/HostBScan wrapper by at least one non-X bit and the width must be the same. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- Interface/select : *port_name*;

  This property defines the name of the port labelled “hostX_select” in Figure 5-12. The specified value may include the %s symbol which is replaced by the id of the HostIjtag wrapper. The default is “host_%s_to_sel”.

- Interface/scan_in : *port_name*;

  This property defines the name of the port labelled “hostX_from_so” in Figure 5-12. The specified value may include the %s symbol which is replaced by the id of the HostIjtag wrapper. The default is “host_%s_from_so”.

Example

This example defines two IJTAG host scan interfaces. The default opcodes and port naming are used.

```
DftSpecification(my_chip,rtl) {
  IjtagNetwork {
    HostScanInterface(tap) {
      Tap(main) {
        HostIjtag(mission) {
        }
        HostIjtag(debug) {
        }
      }
    }
  }
}
```

        }
        DecodedSignal(signal_name) {
        }
      }
    }
  }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a TDR inside the IJTAG network.

Figure 5-15 on page 176 shows the detailed schematic of a 3-bit TDR with some data-in and data-out ports as well as some decoded output signals. When requesting data-out ports or decoded signals, the default is to always use an update stage between the shift stage and the output port. In the case of decoded signals, the decoding logic is between the shift stage and the update stage. It is possible to request that the update stage be removed in situations where it does not matter that the data bits toggle during the shift cycles. See the description of the output_timing property found in the DataOutPorts and DecodedSignal sections. On the other hand, if the output data bit is used to enable or disable parts of the IJTAG network, its output timing must be further delayed by an extra cycle to avoid the race condition described in the Update Stage Timing section that follows. The TCK clock only needs to be balanced within the TDR module but can tolerate as much as 50% of a TCK period between nodes since a negative edge retiming flip-flop is used on the scan-out port of the Tdr and Sib nodes.

The TDR module names are hardcoded to <design_name>_<design_id>_tessent_tdr_<id>.

Update Stage Timing

The IJTAG network can be seen as very similar to a 1149.1 or a 1500 network. It has, however, one extra level of freedom where a TDR bit can be used to enable or disable a part of the

network while that part of the network is also active. In 1149.1, you never need to worry about races on the select lines because you are in the IR states when changing the instruction and it is only used the next time you go to the DR states. In 1500, the WIR and the selected TDR are accessed in a mutually exclusive manner as controlled by the selectWIR signal.

In IJTAG, you do not have this restriction. If you look at the schematic in Example 5-7 on page 139, you can see that while you are loading the green TDR, you may also be loading into the black TDR a value that will take out the green TDR for the next scan load and, instead, select the red TDR. As the black, green and red TDRs all receive the same update_en signal, it is important that the select signal reaching the green TDR is still active by the time the falling edge of TCK reaches the green TDR. It is also important that the select signal reaching the red TDR is still inactive by the time the falling edge of TCK reaches the red TDR.

If these conditions are not met, the green TDR may not perform its last update and the red update stage may be prematurely disturbed. This racing condition is illustrated in Figure 5-14. The source box can be seen as the black TDR while the destination box can be seen as the green TDR in Figure 5-7 on page 139. If you have skew in the TCK clock distribution where TCK2 is delayed with respect to TCK1, the update stage value labelled S1 could change too soon and block the overlap of S1 and update_en at the destination update flip-flop. Because the enabling can be going in all directions, you either have to precisely balance your TCK clock network all over the network or do as is done in Tessent Shell and add an extra delay stage for those select signals to remove the race condition even in the presence of large TCK clock skew.

Figure 5-14. Update Stage Timing Diagram

Parameters

- *id*

  A unique id that contains only letters, numbers and underscores. Every Tdr wrapper must have a different *id* inside the IjtagNetwork wrapper.

- parent_instance : *instance_name;*

  A string property that specifies the parent instance in which to instantiate the TDR module. When left unspecified, the TDR is instantiated in the common ancestor of the DataInPorts, DataOutPorts, and DecodedSignal connections. You can use this property to push a TDR down into a different location. You can specify "." as the parent_instance to force the TDR to be placed in the root module independent of the DataInPort, DataOutPort, and DecodedSignal connections. When the TDR has no DataInPorts and DataOutPorts connections, the parent_instance property defaults to the root module.

  If the specified or inferred instance_name is an instance of a repeated module, a warning is displayed during validation and a uniquify_instances command is automatically issued as part of the insertion process to uniquify the instance_name.

  To perform IjtagNetwork insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion

process can be done by going back and forth between setup and insertion mode within a single Tessent Shell invocation. You simply change the current design using the set_current_design command in setup mode.

- leaf_instance_name : *leaf_instance_name*;

  A string property that specifies the leaf instance name of the TDR. It defaults to "<design_name>_<design_spec_id>_tessent_tdr_<tdr_id>_inst" when unspecified. The *dft_spec_id* string is the *id* specified in the DftSpecification wrapper, and the *tdr_id* string is the *id* of the TDR. Tessent Shell checks for conflicts before instantiating the TDR and, if needed, applies the uniquification suffix specified by the set_insertion_options command.

- keep_active_during_scan_test : on | off | auto;

  A property that specifies that all nodes serially connected to the TDR are to be kept active during scan test modes. For information about when to use this property, see section "Scan Testability of the IJTAG Network" on page 117. This property defaults to on when the id is named "scan_modes".

- length : *integer*;

  A property to request a specific shift register length. By default, the length is determined to be large enough to satisfy the specified DataInPorts/count, DataOutPorts/count or DecodedSignal/decode_values properties.

- extra_bits_capture_value : 0 | 1 | self;

  A property that applies to the upper bits of the TDR when the length is larger than the DataInPorts/count value. The specified values control what the extra shift register bits capture during the capture cycle. The value self means that it will hold its value.

- reset_value : *binary;*

  A property that specifies a binary number as wide as the TDR to specify the reset value of the DataOutPorts and the DecodedSignals. The shift register stage is not reset. The ICL description of the TDR automatically sets the DefaultLoadValue of the ScanRegister equal to the specified reset value such that if a TDR bit resets to 1, the DefaultLoadValue for that bit will also be set to 1.

- Attributes/*attribute_name* : *attribute_value*;

  A data wrapper that defines arbitrary attributes in the TDR ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using get_attribute_value_list, you must have registered the attribute using the "register_attribute -object_type icl_module" command. For example, assuming you have registered the att1 attribute on the icl_module object type, and you have added the att1 attribute with a value of "v1" in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the "get_icl_modules -filter att1==v1" command.

Example

The following example illustrates the syntax used to create a TDR exactly like the one shown in Figure 5-15. Notice how the output_timing property is used to make some of the outputs unlatched and some having the extra delay stage needed for ijtag_scan_selection.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Tdr(blue) {
        length                    : 3;
        extra_bits_capture_value : self;
        DataOutPorts {
          count             : 3;
          port_naming       : Dout[%d];
          output_timing(0)  : ijtag_scan_selection;
          output_timing(1)  : normal;
          output_timing(2)  : unlatched;
        }
        DataInPorts {
          count             : 1;
          port_naming       : Din%d;
        }
        DecodedSignal(sigA) {
          decode_values     : 3'bx00;
          output_timing     : ijtag_scan_selection;
        }
        DecodedSignal(sigB) {
          decode_values     : 3'bx01;
          output_timing     : normal;
        }
        DecodedSignal(sigC) {
          decode_values     : 3'bx1x;
          output_timing     : unlatched;
        }
      }
    }
  }
}
```

Tdr/DataInPorts

Syntax

```
IjtagNetwork {
  HostScanInterface(id) {
    Tdr(id) {
      DataInPorts {
        count              : integer;          // default: auto
        port_naming        : port_naming, ...;//default: ijtag_data_in[%d]
        connection(range) : pin_name;
      }
    }
  }
}
```

Description

A wrapper that specifies the number (count) of data-in ports to create on the TDR, the naming of the ports, and the connections to make to them.

Parameters

- count : *integer;*

  A property that specifies the number of data-in bits needed on the TDR. By default, the count is determined to be large enough to satisfy the *range* value of all connection properties.

- port_naming : *port_naming, ...;*

  A property that specifies the naming of the data-in ports. The port_naming value has two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

  When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Din%2d will create Din00, Din01, Din02, and so on. Din%d and Din%1d mean the same thing. The default is “ijtag_data_in[%d]”.

  When using a list of port names, you control the exact naming and width of each data-in port. For example, if you specify “locked”, you will get exactly one data-in port called “locked” as illustrated in Example 2.

- connection*(range) : pin_name;*

  A repeatable property that specifies the connections to make between the bits of the data-in ports and the existing pins inside the design. Because data-in ports are sinks, the same bit cannot be connected to multiple sources. It is, therefore, illegal to repeat the connection property with overlapping range indexes.

  If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the process_dft_specification -no_insertion option is not used. If you are using

the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Example 1

The following example illustrates the specification of two data-in ports with connections to pins on a design instance.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Sib(orange) {
        Tdr(orange) {
          DataInPorts {
            connection(0) : u2/top_green/go;
            connection(1) : u2/top_green/done;
          }
        }
      }
    }
  }
}
```

Example 2

The following example illustrates the explicit naming of the data-in and data-out ports. The data-in port is a single bit wide and called “locked”. There are 7 data-out ports. The port associated with connection(0) is div[0] and the one associated with connection(5) is mult[2].

```
DftSpecification(clk_gen,bottom_up) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Tdr(1) {
        DataOutPorts {
          connection(5:3) : pll/mult[2:0];
          connection(2:0) : pll/div[2:0];
          port_naming     : mux_sel, mult[2:0], div[2:0];
        }
        DataInPorts {
          connection(0) : pll/locked;
          port_naming   : locked;
        }
      }
    }
  }
}
```

      DataInPorts {
        count              : integer;
        port_naming        : port_naming, ...; //default:ijtag_data_out[%d]
        multiplexing       : on | off | auto;
        output_timing(range) : timing_spec; // repeatable
        connection(range)    : pin_name;    // repeatable
      }
    }
  }
}
```

Description

A wrapper that specifies the number (count) of data-out ports to create on the TDR, the naming of the ports, the output_timing of the ports, and the connections to make to them.

Parameters

- count : *integer*;

  A property that specifies the number of data-out bits needed on the TDR. By default, the count is determined to be large enough to satisfy the *range* value of all connection properties.

- port_naming : `port_naming, ...;`

  A property that specifies the naming of the data-out ports. The port_naming value has two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

  When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Dout%2d will create Dout00, Dout01, Dout02, and so on. Dout%d and Dout%1d mean the same thing. The default is “ijtag_data_out[%d]”.

  When using a list of port names, you control the exact naming and width of each data-out port. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly seven data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in Example 2.

- multiplexing : `on | off | auto;`

  A property that specifies whether to add a multiplexer when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added to control the

select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See Example 2 for illustration.

- output_timing (*range*) : unlatched | normal | ijtag_scan_reconfiguration;

  A repeatable property that specifies the output timing of the data-out ports. As you can see in Figure 5-15, a data-out port can be directly connected to the shift register when output timing is specified as unlatched. This corresponds to Dout[2] in Figure 5-15. A data-out port can be connected to the shift register though an update stage when output timing is specified as normal. This corresponds to Dout[1] in Figure 5-15. A data-out port can be connected to the shift register though an update stage and another delay stage when output timing is specified as ijtag_scan_reconfiguration. This corresponds to Dout[0] in Figure 5-15. For a description of when the delay stage is needed, refer to the "Update Stage Timing" section.

- connection`(range)` : `pin_name`;

  A repeatable property that specifies connections to make between bits of the data-out ports and existing pins inside the design. Because data-out ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.

  If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the process_dft_specification -no_insertion option is not used. If you are using the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Example 1

The following example illustrates the specification of four data-out ports with connections to pins on a design instance. The example associated with Figure 5-15 shows the use of the output_timing property.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Sib(orange) {
        Tdr(orange) {
          DataOutPorts {
            connection(0)   : u2/top_green/en;
            connection(3:1) : u2/top_green/mode[2:0];
          }
        }
      }
    }
  }
}
```

Example 2

The following example illustrates the explicit naming of the data-in and data-out ports. The data-in port is a single bit wide and called "locked". There are 7 data-out ports. The port associated with connection(0) is div[0] and the one associated with connection(5) is mult[2].

Multiplexing is left unspecified so it defaults to auto. Because the pll/mult[2:0] and pll/div[2:0] pins have a functional source, a multiplexer is inserted and a 7th data-out bit named mux_sel is used to control the multiplexers.

```
DftSpecification(clk_gen,bottom_up) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Tdr(1) {
        DataOutPorts {
          connection(5:3) : pll/mult[2:0];
          connection(2:0) : pll/div[2:0];
          port_naming     : mux_sel, mult[2:0], div[2:0];
        }
        DataInPorts {
          connection(0) : pll/locked;
          port_naming   : locked;
        }
      }
    }
  }
}
```

Tdr/DecodedSignal

Syntax

```
IjtagNetwork {
  HostScanInterface(id) {
    Tdr(id) {
      DecodedSignal(signal_name) {
        decode_values : binary_code, ...;
        multiplexing  : on | off | auto;
        output_timing : timing_spec;
        connection    : port_pin_name;       // repeatable
        Attributes {
          attribute_name : attribute_value;

      }
    }
  }
}
```

Description

A wrapper that specifies the creation of a decoded signal.

The decode_values property is used to specify which values of the TDR make the decoded signal active. The connection property specifies connections from the decoded signals.

Parameters

- decode_values : *binary_code*, ...;

  A property that specifies a list of binary codes that define when the decoded signal is active. The binary codes must be as wide as the TDR. The binary numbers may contain Xs as long as there is at least one 0 or one 1 in each value.

- multiplexing : *on* | *off* | *auto*;

  A property that specifies whether to add a multiplexer when making the connection to the specified *pin_name* of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added on the TDR to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified *pin_name* of the connection properties. See Example 2 of the Tdr/DataOutPorts section for an illustration of this.

- output_timing : *unlatched* | *normal* | *ijtag_scan_selection*;

  A property that specifies the output timing of the decode signal port. As you can see in Figure 5-15:

  - A decoded signal is directly connected to the decoding logic when output timing is specified as unlatched; this corresponds to SigC.
  - A data-out port is connected to the decoding logic though an update stage when output timing is specified as normal; this corresponds to SigB.

- A data-out port is connected to the decoding logic though an update stage and another delay stage when output timing is specified as ijtag_scan_reconfiguration; this corresponds to SigA.

Refer to the "Update Stage Timing" section for a description of when the delay stage is needed.

- connection : *port_pin_name*;

  A repeatable property that specifies connections to make between the decoded signal and existing pins inside the design. Because decoded signals are sources, they can be connected to multiple destinations by simply repeating the connection property.

- Attributes/attribute_name : *attribute_value*;

  A data wrapper that defines arbitrary attributes on the ICL port associated with the decoded signal. This mechanism is useful for finding special attributed ports in the concatenated ICL. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be be able to introspect its value using get_attribute_value_list, you must have registered the attribute using the "register_attribute -object_type icl_module" command. For example, assuming you have registered the att1 attribute on the icl_port object type, and you have added the att1 attribute with a value of "v1" to some DecodedSignal ports of your TDR modules using the above Attributes wrapper, you can later quickly find those ports using the "get_icl_ports -of *module_name* -filter att1==v1" command. The icl_port attributes are also inherited by the icl_pin objects so you can also find the pins using "get_icl_pins -filter att1==v1".

Example

The following example illustrates the creation of three decoded signals with each having a different output timing. The example corresponds to the schematic shown in Figure 5-15.

```
DftSpecification(MyCore,rtl) {
  IjtagNetwork {
    HostScanInterface(purple) {
      Tdr(blue) {
        DecodedSignal(sigA) {
          decode_values    : 3'bx00;
          output_timing    : ijtag_scan_selection;
        }
        DecodedSignal(sigB) {
          decode_values    : 3'bx01;
          output_timing    : normal;
        }
        DecodedSignal(sigC) {
          decode_values    : 3'bx1x;
          output_timing    : unlatched;
        }
      }
    }
  }
}
```

Tdr/DataOutPorts

Tdr/Interface

Syntax

```
IjtagNetwork {
  HostScanInterface(id) {
    Tdr(id) {
      Interface {
        select : port_name;  // default: ijtag_sel
        tck    : port_name;  // default: ijtag_tck
        scan_in: port_name;  // default: ijtag_si
        scan_out: port_name;  // default: ijtag_so
        reset  : port_name;  // default: ijtag_reset
        reset_polarity: active_high | active_low;
        shift_en: port_name;  // default: ijtag_se
        capture_en: port_name;  // default: ijtag_ce
        update_en: port_name;  // default: ijtag_ue
      }
    }
  }
}
```

Description

A wrapper that provides properties to fully specify the names of the eight client ports of the TDR.

The wrapper also allows defining the active polarity of the reset port.

Parameters

- select : *port_name;*

  This property defines the name of the select port. The default is “ijtag_sel”.

- tck : *port_name;*

  This property defines the name of the tck port. The default is “ijtag_tck”.

- scan_in : *port_name;*

  This property defines the name of the scan_in port. The default is “ijtag_si”.

- scan_out : *port_name;*

  This property defines the name of the scan_out port. The default is “ijtag_so”.

- reset : *port_name;*

  This property defines the name of the reset port. The default is “ijtag_reset”.

- reset_polarity : active_high | active_low;

  This property defines the active polarity of the reset port. The default is “active_low”.

- shift_en : *port_name;*

  This property defines the name of the shift_en port. The default is “ijtag_se”.

- capture_en : *port_name;*

  This property defines the name of the capture_en port. The default is “ijtag_ce”.

- update_en : *port_name;*

  This property defines the name of the update_en port. The default is “ijtag_ue”.

Example

The following example illustrates fully specifying a unique name for each port of the TDR.

```
Tdr(id) {
  Interface {
    select     : sel;
    tck        : tck;
    scan_in    : si;
    scan_out   : so;
    reset      : reset;
    shift_en   : se;
    capture_en : ce;
    update_en  : ue;
  }
}
```

DefaultsSpecifications Configuration Syntax

This section describes the configuration data syntax used inside Tessent Shell to specify default values used by the create_dft_specification command. Tessent Shell comes with built-in default values for all configuration properties. You can use the DefaultsSpecification wrapper to change many of those default values to match your preferences and requirements.

This default-setting mechanism also comes with a hierarchy of DefaultsSpecification wrappers that enable you to have company, group, and user-level defaults. In your .tessent_startup file, you can load three configuration files: one containing a DefaultsSpecification(company) wrapper, one containing a DefaultsSpecification(group) wrapper, and one containing a DefaultsSpecification(user) wrapper. The final default value of a given property is taken from the DefaultsSpecification(user) wrapper, if the property is specified in that wrapper; it is taken from the DefaultsSpecification(group) wrapper if it is defined in that wrapper but not in the DefaultsSpecification(user) wrapper; and, it is taken from the DefaultsSpecification(company) wrapper when it is defined there but not in the DefaultsSpecification(group) and DefaultsSpecification(user) wrappers. The final default value of a given property is taken from the built-in default value if it is not specified in any of the three DefaultsSpecification wrapper.

Refer to the read_config_data command to read about how to load in configuration data. See the get_defaults_value command to read about how to access the specified defaults values from your dofile. If you prefer, you can also use the “set_defaults_value -policy” command to define your different policies instead of using configuration files.

DefaultsSpecification/DftSpecification

Syntax

```
DefaultsSpecification(policy) { //Legal: company | group | user
  DftSpecification {

    rtl_extension               : string;  // default: v
    gate_extension              : string;  // default: vg
    reuse_modules_when_possible : boolean; // default: auto

    IjtagNetwork {

    }
  }
}
```

Description

A wrapper that specifies options that define the default values of the properties in the DFTSpecification wrapper.

Parameters

- rtl_extension : *string*;

  A string that specifies the default value for the corresponding property found inside the DftSpecification wrapper.

- gate_extension : *string*;

  A string that specifies the default value for the corresponding property found inside the DftSpecification wrapper.

- reuse_modules_when_possible : *boolean*;

  A string that specifies the default value for the corresponding property found inside the DftSpecification wrapper.

Example

The following example shows a GlobalOptions wrapper that specifies the rtl_extension as “vb” and the gate_extension as ”v” inside the group defaults policy. Because is is not overridden by a user defaults policy wrapper, those default values are used by the create_dft_specification command.

```
> read_config_data -from_string {
  DefaultsSpecification(user) {
    DftSpecification {
      rtl_extension   : vb;
      gate_extenstion : v;
    }
  }
}
> get_defaults_value DftSpecification/rtl_extension
vb
```

IjtagNetwork

Syntax

```
DefaultsSpecification(policy) { //Legal: company | group | user
  DftSpecification {
    IjtagNetwork {
      HostScanInterface {
        Block {
          tck             : port_name;  // default: ijtag_tck
          reset           : port_name;  // default: ijtag_reset
          select          : port_name;  // default: ijtag_sel
          shift_en        : port_name;  // default: ijtag_se
          capture_en      : port_name;  // default: ijtag_ce
          update_en       : port_name;  // default: ijtag_ue
          scan_in         : port_name;  // default: ijtag_si
          scan_out        : port_name;  // default: ijtag_so
        }
        Chip {
          tck             : port_name;  // default: tck
          tdi             : port_name;  // default: tdi
          tdo             : port_name;  // default: tdo
          tms             : port_name;  // default: tms
          trst            : port_name;  // default: trst
        }
      }
    }
  }
}
```

Description

A wrapper that is used to specify defaults value of properties found in the DftSpecification/IjtagNetwork wrapper.

The properties found in the HostScanInterface/Block wrapper are used to define the Interface of the HostScanInterface when the design level is set to “physical_block” or “sub_block” using the set_design_level command. The properties found in the HostInterface/Chip wrapper are used to define the Interface of the HostScanInterface when the design level is set to “chip”.

Parameters

- ScanInterface/Block/tck : *port_name*;

  A property that sets the default value of the tck property found inside the HostScanInterface/Interfacewrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during create_dft_specification when design level is physical_block or sub_block.

- ScanInterface/Block/reset : *port_name*;

  A property that sets the default value of the reset property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during create_dft_specification when design level is physical_block or sub_block.

- ScanInterface/Block/select : *port_name*;

  A property that sets the default value of the select property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when design level is physical_block or sub_block.

- ScanInterface/Block/shift_en : *port_name*;

  A property that sets the default value of the shift_en property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.

- ScanInterface/Block/capture_en : *port_name*e;

  A property that sets the default value of the capture_en property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.

- ScanInterface/Block/update_en : *port_name*;

  A property that sets the default value of the update_en property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.

- ScanInterface/Block/scan_in : *port_name*;

  A property that sets the default value of the scan_in property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.

- ScanInterface/Block/scan_out : *port_name*;

  A property that sets the default value of the scan_out property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.

- ScanInterface/Chip/tck : *port_name*;

  A property that sets the default value of the tck property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is chip.

- ScanInterface/Chip/trst : *port_name*e;

  A property that sets the default value of the trst property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The

default value is used during the create_dft_specification command when the design level is chip.

- ScanInterface/Block/tms : *port_name*;

  A property that sets the default value of the tms property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is chip.

- ScanInterface/Block/tdi : *port_name*;

  A property that sets the default value of the tdi property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is chip.

- ScanInterface/Block/tdo : *port_name*;

  A property that sets the default value of the tdo property found inside the HostScanInterface/Interface wrapper of the DftSpecification/IjtagNetwork wrapper. The default value is used during the create_dft_specification command when the design level is chip.

Example

The following wrappers define custom naming convention for the IJTAG ports that serves as the default for the entire company:

```
DefaultsSpecification(company) {
  DftSpecification {
    IjtagNetwork {
      HostScanInterface {
        Block {
          tck             : my_tck;
          reset           : my_reset;
          select          : my_select;
          shift_en        : my_shift_en;
          capture_en      : my_capture_en;
          update_en       : my_update_en;
          scan_in         : my_scan_in;
          scan_out        : my_scan_out
        }
        Chip {
          tck             : my_tck;
          tdi             : my_tdi;
          tdo             : my_tdo;
          tms             : my_tms;
          trst            : my_trst;
        }
      }
    }
  }
}
```

Metadata Configuration Syntax

This section describes the configuration metadata syntax used inside Tessent Shell to define all valid configuration syntax. The metadata syntax is used to define all of the available syntax documented in the DftSpecification and DefaultsSpecification/DftSpecification wrappers. The metadata syntax is also used to create the configuration tree widgets in DFTVisualizer that are used to edit and view the configuration data in the Configuration Data window. For information about how to load configuration data in the DFTVisualizer Configuration Data window, see the add_config_tab and display_specification commands. Finally, the metadata is used by the report_config_syntax command to report the available syntax in a human-readable format that is consistent with how the syntax is documented in this reference guide.

You typically do not need to define metadata because all configuration data is fully defined in the tool. You can, however, define your own metadata to define any configuration syntax needed to automate portions of your flows. Both DFTVisualizer and the report_config_syntax command, which are driven by the metadata, will completely support your syntax.

You can also augment the metadata of the DftSpecificationfor your custom needs. The added elements will be ignored by the process_dft_specification command. You can then add your own code to access the added properties and use it for your custom needs. For example, you may want to package a fully-specified DftSpecification file for an RTL core such that the user of the core can simply add the DFT hardware by running process_dft_specification with your packaged DftSpecification file. In this file, you may want to define extra information such as clock sources with their periods. After you have done this, you can use the configuration data commands such as the get_config_value command to access the information and issue the add_clocks commands in your flow. You can also add extra information that is accessed by your process_dft_specification.post_insertion Procedure and have it automatically perform custom actions based on the captured information in the DftSpecification file.

Wrapper

Syntax

```
Partitions : partition_list; //Only on first line of file
Wrapper(wrapper_name) {

  Repeatable        : On | Off | Single;
  IgnoreUnknows     : On | Off;
  Usage             : normal | hidden | Env(EnvVar);
  ReferenceableOnly : On | Off;

  InsertFirst;
  InsertLast; // default behavior
  InsertBefore      : meta_leaf_name;
  InsertAfter       : meta_leaf_name;

  Options(Visualizer) {
    cdv_tab_prefix : string;
    DisplayString  : string;
  }

  //Everything below is repeatable and optional

  Id(name_id) {
  }

  Property(property_name) {
  }
  RepeatableProperty(property_name) {
  }
  DataWrapper(wrapper_name) {
  }
  CsvWrapper(wrapper_name) {
  }

  Reference = relative_or_absolute_meta_path;
  ReferenceWithInheritedDefault = relative_meta_path;

}
```

Description

A wrapper used in metadata to define the syntax of a wrapper that is usable in configuration data.

The presence of the Partitions property is used to define the partition in which the wrapper, and all of the elements defined within in it, are to exist.

Parameters

- *Partitions : partition_list;*

  An optional property that can only be specified on the first line of a file, and that controls in which partition the metadata is to be used when defining syntax. When unspecified, the wrappers and what is defined within them, are defined in the default partition.

The partition name can be specified as “default”, “tcd”, or “default, tcd”. The “default” partition is the one in which the DftSpecification and DefaultsSpecification/DftSpecification wrappers exist. The tcd partition is the one in which the files loaded with the read_core_descriptions command are loaded into. The tcd partition is read-only and configuration data found in it cannot be modified using configuration-editing commands such as the add_config_element command.

All existing syntax defined in the “tcd” partition within the tool is also defined in the default partition. If you absolutely need to edit a tcd file, you need to load it into the default partition using the read_config_data command, perform your edits using the editing commands, save it back to the file using write_config_data, and then load it back into the tcd partition using the read_core_descriptions command. Even if it exists in the default partition, the content of this configuration data is not used by the tool because the tool only looks for tcd data in the tcd partition.

- *wrapper_name*

  A required string that defines the name of the wrapper to create. The string must start with a letter and only include letters, numbers, and underscores. The wrapper_name must be unique across all wrapper_names for root-level wrappers inside a partition, and across all wrapper_names and property_names found within a common parent wrapper.

  When you want to define extra syntax inside an already defined wrapper, you create a wrapper that contains your new elements and has a “/” as the first character. For example, if you wanted to add a new wrapper called MyCustomData inside DftSpecification/IjtagNetwork, you would do it this way:

```
Wrapper(/DftSpecification/IjtagNetwork) {
  Wrapper(MycustomData) {
    ...
  }
}
```

- Repeatable : On | Off | Single;

  A property used to define whether the wrapper is repeatable. Both the Off and Single options mean that the wrapper is not repeatable. The difference between Off and Single is that a wrapper identified as “Repeatable : Single” always exists whether or not it is specified in the configuration data. You can get the value of properties inside a Single wrapper without having to first check if the wrapper exists or not. A “Repeatable : Off” wrapper does not exist until it is specified.

- IgnoreUnknowns : On | Off;

  A property used to specify that wrappers and properties not declared in the metadata of this wrapper are to be tolerated in this wrapper. You should never set this On in wrappers that are not purely machine generated and consumed by a machine as any typos will go unnoticed and will be silently ignored. These unknown elements will not be viewable and editable in DftVisualizer and report_config_syntax will not report their syntax. It is much safer to define all allowed syntax within a wrapper even if you choose to keep some hidden using the “Usage : hidden;” property which documented next.

- Usage : normal | hidden | Env(*EnvVar*);

  A property that controls the visibility of a wrapper. When set to normal, the wrapper is reported by report_config_syntax and visible in DFTVisualizer. When set to hidden, the wrapper is not reported by report_config_syntax and is invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands such as get_config_value if the name of the hidden element is known to the user. The "Usage : Env(*EnvVar*)" is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise, it is treated as hidden.

- ReferenceableOnly : On | Off;

  A property that controls the existence of the wrapper. When set to On, this wrapper definition does not exist when it is defined. It and its children only exist when referenced using the Reference property . This option is useful to create a wrapper that defines a library of elements to be referenced from other wrappers.

- InsertFirst;

  An implicit Boolean property used to specify that the wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which wrappers with "Repeatable : Single" gets displayed in the configuration tabs inside Dft Visualizer.

- InsertLast;

  An implicit Boolean property used to specify that the wrapper is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which wrappers with "Repeatable : Single" gets displayed in the configuration tabs inside DftVisualizer.

- InsertBefore : *meta_leaf_name*;

  A property used to specify that the wrapper is to be inserted before an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a wrapper before Wrapper(IjtagNetwork), you would specify "InsertBefore : IjtagNetwork;". This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which wrappers with "Repeatable : Single" are displayed in the configuration tabs inside DftVisualizer.

- InsertAfter : *meta_leaf_name*;

  A property used to specify that the wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a wrapper after Wrapper(IjtagNetwork), you would specify "InsertAfter : IjtagNetwork;". This is useful when you are trying to insert extra metadata into an already existing wrapper.

The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which wrappers with “Repeatable : Single” are displayed in the configuration tabs inside DftVisualizer.

- Options(Visualizer)/cdv_tab_prefix : *string*;

  A property used to control the name of the Tab that is used by DftVisualizer when the add_config_tab command is issued on this wrapper. The specified prefix is concatenated with an integer incremented from 1 for all added configuration tabs having a common prefix.

- Options(Visualizer)/DisplayString : *string*;

  A property used to control how the wrapper is labelled in the Configuration Data window. When unspecified, it default to *wrapper_name*. This option is useful when you want to create a GUI to display configuration data and you want to name the tree nodes using sentences as oppose to the strict wrapper names.

- Reference = relative_or_absolute_meta_path;

  A property used to define an element inside the wrapper using the same definition that was used inside another wrapper. This not only allows you to keep the metadata DRY, it also enables the element to be moved or copied from one location to the other using DFTVisualizer or the “add_config_element -copy_from” and the move_config_element commands. For an element to be copied or moved from one wrapper to the next, the metadata definition in both places must be created in one place by either having both of them reference a unique definition, or by having one definition reference the other. The path may be absolute or relative such as in these two examples:

  ```
  Reference = ../Interface/scan_in;
  Reference =
  /DftSpecification/IjtagNetwork/HostScanInterface/Interface/scan_in;
  ```

- ReferenceWithInheritedDefault = *relative_meta_path*;

  A property used to define a property inside the wrapper using the same definition that was used inside another wrapper. Not only is the definition inherited, the value of the referenced property becomes the default value of the new property. To use this feature, the *relative_meta_path* can only come back down in wrappers specified with “Repeatable : Single”; this is because to be able to inherit the default value from it, the referenced property must always exist whenever the referencing property exists. For example, the path *../../Interface/scan_in* is legal because Interface is defined with “Repeatable : Single” inside the IjtagNetwork/HostScanInterface wrapper. The above example could be used to create a property called “scan_in” in a wrapper found inside HostScanInterface that defaults to the value of the “../../Interface/scan_in” property when the “./scan_in” property is not specified.

Example

The following example defines the metadata used by the Sib wrapper inside the DftSpecification/IjtagNetwork wrapper. Following is the constructed syntax reported by

report_config_syntax on the same wrapper. Notice the recursive definition of the Sib node inside the Sib node achieved by referencing itself using “Reference = ../Sib;”.

```
> report_config_data -partition meta \
       /dftspecification/ijtagnetwork/hostscaninterface/sib

}
```

Description

A wrapper used in metadata to define a property that is usable in configuration data.

A property exists as soon as its parent wrapper exists regardless of whether the property is specified or not.

Parameters

- Usage : normal | hidden | Env(*EnvVar*);

  A property that controls the visibility of the property. When set to normal, the property is reported by the report_config_syntax command and is visible in DFTVisualizer. When set to hidden, the wrapper is not reported by report_config_syntax and is invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands, such as the get_config_value command, if the name of the hidden property is known by the user. The “Usage : Env(*EnvVar*)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise, it is treated as hidden.

- InsertFirst;

  An implicit Boolean property used to specify that the property is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which properties are displayed in the Configuration Option panel inside DftVisualizer.

- InsertLast;

  An implicit Boolean property used to specify that the property is to be inserted after the already existing elements in the wrapper. This is useful if you are trying to insert extra

metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which properties are displayed in the Configuration Option panel in DftVisualizer.

- InsertBefore : *meta_leaf_name*;

  A property used to specify that the property is to be inserted before an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a property before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which properties get displayed in the Configuration Options panel in DftVisualizer.

- InsertAfter : *meta_leaf_name*;

  A property used to specify that the property is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a property after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which properties get displayed in the Configuration Options panel in DftVisualizer.

- Options(Visualizer)/DisplayString : *string*;

  A property used to control how the property is identified in the GUI. When unspecified, it defaults to *property_name*. This option is useful when you want to create a GUI to display configuration data and you want to name the properties using sentences as opposed to the strict property name.

- Options(Visualizer)/BlankSpaceAbove : On | Off;

  A property used to control the insertion of a blank space above the property when creating the Configuration Options panel. You can see its effect in the panel shown in Figure 5-17 on page 203. The option was specified inside the tck, reset, trst and daisy_chain_with_existing_client property wrappers.

Figure 5-17. Example Option panel where blank spaces were added

Example

The following example defines properties of all types. It is used in the example of the get_config_value command to illustrate how to introspect them. You can use report_config_data DftSpecification -partition meta to see many more examples.

```
Wrapper(SingularWrapper) {
  Repeatable : single;
  Wrapper(WrapperWithRepeatableId) {
    id(name*) {
      type : string;
    }
    Reference = /SingularWrapper/WrapperWithRepeatableId;
    Property(time_property) {
      Value(time) {
        type : time;
        DefaultValue : 3.5ns;
      }
    }
    Property(integer_property) {
      Value(integer) {
        type : int;
        DefaultValue : 3;
      }
    }
    Property(binary_property) {
      Value(binary) {
        type : binary;
        DefaultValue : 3'b0;
```

```
          }
        }
        Property(string_property) {
          Value(string*) {
            type : string;
            DefaultValue : "";
          }
        }
        CSVWrapper(CsvWrapper) {
          Repeatable : on;
          id(module_name) {
            Type : String;
          }
          id(design_id) {
            Type : String;
            IgnoreCase : On;
          }
        }
        DataWrapper(DataWrapper_with_no_value) {
          RowIdElement(port) {
            Type : String;
            repeatable : on;
          }
        }
        DataWrapper(DataWrapper_value) {
          RowIdElement(port) {
            Type : String;
            repeatable : on;
          }
          Value(period) {
            Type : time;
          }
        }
      }
    }
```

DataWrapper

report_config_syntax

RepeatableProperty

CsvWrapper

RepeatableProperty

Syntax

```
Wrapper(wrapper_name) {
  RepeatableProperty(property_name) {
    Usage    : normal | hidden | Env(envVar);

    InsertFirst;
    InsertLast; //default
    InsertBefore : meta_leaf_name;
    InsertAfter  : meta_leaf_name;

    Options(Visualizer) {
      DisplayString   : string;
    }
    Id(id) { //repeatable and optional
    }
    Value(value_id) { //repeatable, minimum one
    }
  }
}
```

Description

A wrapper used in metadata to define a repeatable property that is usable in configuration data.

As opposed to normal properties, a repeatable property has no default values and does not exist until it is specified.

Parameters

- Usage : normal | hidden | Env(*EnvVar*);

  A property that controls the visibility of a property. When set to normal, the property is reported by report_config_syntax and visible in DFTVisualizer. When set to hidden, the wrapper is not reported by report_config_syntax and invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands such as the get_config_value command if the name of the hidden property is known to the user. The “Usage : Env(*EnvVar*)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise it is treated as hidden.

- InsertFirst;

  An implicit Boolean property used to specify that the property is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the properties gets displayed in the Configuration Options panel in DftVisualizer.

- InsertLast;

  An implicit Boolean property used to specify that the property is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra

metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the properties gets displayed in the Configuration Options panel in DftVisualizer.

- InsertBefore : *meta_leaf_name*;

  A property used to specify that the property is to be inserted before an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a property before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the properties get displayed in the Configuration Options panel in DftVisualizer.

- InsertAfter : *meta_leaf_name*;

  A property used to specify that the property is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a property after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the properties get displayed in the Configuration Options panel in DftVisualizer.

- Options(Visualizer)/DisplayString : *string*;

  A property used to control how the folding region associated to a repeatable property is identified in the Configuration Data window. When unspecified, it defaults to *property_name*. A convention of using lower case name with underscore is employed when naming normal and repeatable properties in the tool. The convention for the folding region name in DftVisualizer is to use Camel naming. This is achieved by using this option.

Example

The following example shows how the connection property is defined inside the Tdr wrapper.

```
> report_config_data [get_config_value Tdr/DataOutPorts/Connection \
        -in_wrapper /DftSpecification/IjtagNetwork/HostScanInterface \
        -partition meta -object]

RepeatableProperty(connection) {
  Options(Visualizer) {
    DisplayString : Connections;
  }
  Id(range) {
    Type : string;
    Repeatable : On;
  }
  Value(pin_name) {
    Type : string;
    Repeatable : On;
  }
}
```

DftSpecification

DataWrapper

report_config_syntax

Property

CsvWrapper

DataWrapper

Syntax

```
Wrapper(wrapper_name) {
  DataWrapper(wrapper_name) {
    Usage              : normal | hidden | Env(envVar);

    InsertFirst;
    InsertLast; //default
    InsertBefore       : meta_leaf_name;
    InsertAfter        : meta_leaf_name;

    Options(Visualizer) {
      DisplayString    : string;
    }
    RowIdElement(element_id) { // not_repeatable, required
    }
    Value(value_id) { // repeatable, optional
    }
  }
}
```

Description

A wrapper used in metadata to define a data wrapper that is usable in configuration data.

As opposed to a normal wrapper, a data wrapper contains only data rows composed of arbitrary row id element with optional values. This type of wrapper is useful to associate values to arbitrary elements such as ports:

```
ClockPeriods {
  clka : 4ns;
  clkb : 3ns;
}
```

A data wrapper is like a wrapper with “Repeatable : Single”. It is not repeatable and starts to exist as soon as its parent wrapper exists.

Parameters

- Usage : normal | hidden | Env(*EnvVar*);

  A property that controls the visibility of the data wrapper. When set to normal, the data wrapper is reported by report_config_syntax and visible in DFTVisualizer. When set to hidden, the data wrapper is not reported by report_config_syntax and invisible in DFTVisualizer. Its content can still be fetched and edited using the configuration instrospection and editing commands such as the get_config_value command if the name of the hidden data wrapper is known to the user. The “Usage : Env(*EnvVar*)” is treated as normal if the EnvVar environment variable is defined and set to 1 otherwise it is treated as hidden.

- InsertFirst;

  An implicit Boolean property used to specify that the data wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert

extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the data wrappers get displayed in the Configuration Options panel inside DftVisualizer.

- InsertLast;

  An implicit Boolean property used to specify that the data wrapper is to be inserted after all already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command; it also controls the order in which folding regions associated to the data wrappers get displayed in the Configuration Options panel inside DftVisualizer.

- InsertBefore : *meta_leaf_name*;

  A property used to specify that the data wrapper is to be inserted before an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a data wrapper before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which folding regions associated to the data wrappers get displayed in the Configuration Options panel inside DftVisualizer.

- InsertAfter : *meta_leaf_name*;

  A property used to specify that the data wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a data wrapper after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command. Also, it controls the order in which folding regions associated to the data wrappers get displayed in the Configuration Options panel inside DftVisualizer.

- Options(Visualizer)/DisplayString : *string*;

  A property used to control how the folding region associated to a data wrapper is identified in the Configuration Data window. When unspecified, it defaults to *wrapper_name*. This option is useful when you want to create a GUI to display configuration data and you want to name the folding regions as opposed to the strict data wrapper name.

Example

The following example shows how the ClockPeriods data wrapper shown in the description section above is defined in metadata. Notice the value of type time with the extra allowed symbols sync and sync2x.

```
DataWrapper(ClockPeriods) {
  RowIdElement(clock_port) {
    Repeatable : Off;
    Type       : String;
    IgnoreCase : Off;
  }
  Value(period) {
    Type           : Time;
    AllowedSymbols : sync, sync2x;
  }
}
```

CsvWrapper

report_config_syntax

CsvWrapper

Syntax

```
Wrapper(wrapper_name) {
  CsvWrapper(wrapper_name) {
    Usage        : normal | hidden | Env(envVar);

    InsertFirst;
    InsertLast; //default
    InsertBefore : meta_leaf_name;
    InsertAfter  : meta_leaf_name;

    Id(id) { //repeatable and optional
    }
  }
}
```

Description

A wrapper used in metadata to define a CSV wrapper that is usable in configuration data.

As opposed to a normal wrapper, a CSV wrapper contains only rows composed of arbitrary comma separated values.

```
csv {
  v1,v2,"v3 with spaces or comma";
  v4,v5;
}
```

See the command description of report_config_data and write_config_data to see how the wrapper content can be imported from or exported to Excel. CSV wrappers are not visible nor editable inside DftVisualizer. They are meant to be manipulated graphically inside Excel.

Parameters

- Usage : normal | hidden | Env(*EnvVar*);

  A property that controls the visibility of the CSV wrapper. When set to normal, the wrapper is reported by the report_config_syntax command. When set to hidden, the wrapper is not reported by report_config_syntax. Its value can still be fetched and edited using the configuration instrospection and editing commands such as get_config_value if the name of the hidden CSV wrapper is known to the user. The "Usage : Env(*EnvVar*)" is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise it is treated as hidden.

- InsertFirst;

  An implicit Boolean property used to specify that the CSV wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command.

- InsertLast;

  An implicit Boolean property used to specify that the CSV wrapper is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command.

- InsertBefore : *meta_leaf_name*;

  A property used to specify that the CSV wrapper is to be inserted before the already existing elements in the wrapper. You refer to the element using its leaf_name. For example, to insert a CSV wrapper before Wrapper(IjtagNetwork), you would specify “InsertBefore : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command.

- InsertAfter : *meta_leaf_name*;

  A property used to specify that the CSV wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a CSV wrapper after Wrapper(IjtagNetwork), you would specify “InsertAfter : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the report_config_syntax command.

Example

The following example shows how a generic scratch CSV wrapper is defined in the tool. You can use scratch CSV wrappers to import and introspect CSV data generated by Excel as shown in Example 2 of the report_config_data command.

```
CsvWrapper(csv) {
  Repeatable : On;
  Usage : hidden;
  Id(name) {
    Type : string;
  }
}
```

report_config_syntax

Id

Syntax

```
Wrapper(wrapper_name) {
  Id (name_id) {
    Type           : String | Boolean | Real | Int | Time | Binary;
    LegalString    : string_list;        // For String
    LegalInt       : integer_range_list; // For Int
    LegalReal      : real_range_list;    // For Real
    LegalSize      : int | Unsized;      // For Binary
    AllowedSymbols : string_list;        // For all but String
    IgnoreCase     : On | Off;
    Repeatable     : On | Off;
    Mandatory      : On | Off;

    Option(Visualiser) {
      Counter          : local | global |
                         ParentWrapper(wrapper_name).var_name;
      DefaultValueList : string_list;
    }
  }
  RepeatableProperty(property_name) {
    Id (name_id) {
    }
  }
  CsvWrapper(wrapper_name) {
    Id (name_id) {
    }
  }
}
```

Description

A wrapper used in metadata to define an identifier for named wrappers, repeatable properties, and named CSV wrappers.

Parameters

- *name_id*

  A string used to name the identifier. This name can later be referenced using the "get_config_value -id *name_id*" command.

  The *name_id* must start with a letter, include only letters, numbers and underscores, and may be terminated by an asterisk "*". If the *name_id* ends with an *, the Id is repeatable. If there is more than one Id wrapper, only the last one is allowed to have an * at the end. For example:

  ```
  Wrapper(Step) {
    Id(instance*) {
    }
  }
  ```

  allows Step(u1,u2), where u1 and u2 are repeated instance Ids.

- Type : *value*;

  A property that defines the type of the Id. The allowed types are String, Boolean, Real, Int, Time, and Binary. Ids of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the Verilog syntax: <size>‘b<binary_digits>, ‘b<binary_digits>, <size>‘h<hexadecimal_digits>, and ‘h<hexadecimal_digits>.

- LegalString : *string_list*;

  A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed list will consider casing or not based on the Id’s IgnoreCase property.

- LegalInt : *integer_range_list*;

  A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

- LegalReal : *real_range_list*;

  A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”.

- LegalSize : *int* | Unsized;

  A property that can be used when Type is set to Binary to limit the binary number to a specific size.

- AllowedSymbols : *string_list*;

  A property that can be used when Type is set to anything but String to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols will consider casing or not based on the Id’s IgnoreCase property.

- IgnoreCase : On | Off;

  A property that can be used to make the LegalString and the AllowedSymbols case-insensitive. This option also affects if casing is ignored or not when performing the repeatability check described in the Repeatable property below.

- Repeatable : On | Off;

  A property that controls if a given *name_id* can be repeated or not. The validation of the repeatability will consider casing or not based on the IgnoreCase property documented above.

- Mandatory : On | Off;

  A property used to specify if the Id is required or not. This option can only be specified Off for the second or below Id wrapper, and if the Id wrappers below it are also Off.

- Option(Visualiser)/Counter : local | global | ParentWrapper(*wrapper_name*).*var_name*;

  A property used to define how the Id will be populated automatically when adding the wrapper graphically inside DftVisualizer. When the DefaultValueList reaches the element with a # character, the # character is replaced by an integer. The integer is a counter that is either local to the wrapper, global to the entire root wrapper, or local to a named variable attached to a parent wrapper. For example, Ids defined with a counter as ParentWrapper(*controller*).*memory_interface* will share a counter when found anywhere below a wrapper called "controller". The specified parent wrapper leaf name must exist in the ancestry of the element defining the Id.

- Option(Visualiser)/DefaultValueList : string_list

  A property used to define a list of strings that will be used for the first, second, and so on instances of the wrapper. The string elements may contain any number of letters, numbers and underscores. The last element of the list must include a # character and may be a just a # character. For example, the IjtagNetwork/HostScanInterface/Id(id) is defined with a DefaultValueList of "ijtag, ijtag#". If you add a first HostScanInterface, you will see its Id will be "ijtag". Any other subsequent instances will be labelled ijtag0, ijtag1, etc.

Example

The following example defines a wrapper with two Ids, the second one is repeatable and optional.

```
Wrapper(EX1) {
  Id(name) {
    type : string;
  }
  Id(period*) {
    type : time;
    Mandatory : off;
  }
}
```

report_config_data

RepeatableProperty

Value

Value

Syntax

```
Wrapper(wrapper_name) {

  Property(property_name) {
    Value (value_id) {
      Type           : String | Boolean | Real | Int | Time | Binary |
                       ImplicitBoolean;
      LegalString    : string_list;        // For String
      LegalInt       : integer_range_list; // For Int
      LegalReal      : real_range_list;    // For Real
      LegalSize      : int | Unsized;      // For Binary
      AllowedSymbols : string_list;        // For all but String and
                                           //   ImplicitBoolean
      IgnoreCase     : On | Off;
      Mandatory      : On | Off;
    }
  }
  RepeatableProperty(property_name) {
    Value (value_id) {
    }
  }
  DataWrapper(wrapper_name) {
    Value (value_id) {
    }
  }
}
```

Description

A wrapper used in metadata to define an identifier for values of properties, repeatable properties, and data wrappers.

Parameters

- *value_id*

  A string used to name the value. You can reference this name later by using the "get_config_value -value_id *value_id*" command.

  The *value_id* must start with a letter, include only letters, numbers and underscores and may be terminated by an asterisk "*". If the *value_id* ends with an *, the value is repeatable. If there is more than one Value wrapper, only the last one is allowed to have an * at the end. For example:

  ```
  Property(memory_instances) {
    Value(instance*) {
    }
  }
  ```

  allows "memory_instances : u1, u2;", where u1 and u2 are repeated instance values.

- Type : *value*;

  A property that defines the type of the Value. The allowed types are String, Boolean, Real, Int, Time, Binary, and ImplicitBoolean. Values of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the Verilog syntax: <size>‘b<binary_digits>, ‘b<binary_digits>, <size>‘h<hexadecimal_digits>, and ‘h<hexadecimal_digits>. ImplicitBoolean values are implied true as soon as the property is specified with no value. The property InsertFist in the Property wrapper is an example of a property with Type ImplicitBoolean.

- LegalString : *string_list*;

  A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed list will consider casing or not based on the Value’s IgnoreCase property.

- LegalInt : *integer_range_list*;

  A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

- LegalReal : *real_range_list*;

  A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”.

- LegalSize : *int* | Unsized;

  A property that can be used when Type is set to Binary to limit the binary number to a specific size.

- AllowedSymbols : *string_list*;

  A property that can be used when Type is set to anything but String and ImplicitBoolean to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property for Value is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols will consider casing or not based on the Value’s IgnoreCase property.

- IgnoreCase : On | Off;

  A property that can be used to make the LegalString and the AllowedSymbols case-insensitive.

- Mandatory : On | Off;

  A property used to specify if the Value is required or not. This option can only be specified Off for the second or below Value wrapper, and if the Value wrappers below it are also Off.

Example

The following example defines a property with two values; the second one is repeatable and optional.

```
Property(EX1) {
  Value(name) {
    type : string;
  }
  Value(period*) {
    type : time;
    Mandatory : off;
  }
}
```

RowIdElement

Syntax

```
DataWrapper(wrapper_name) {
  RowIdElement (element_id) {
    Type           : String | Boolean | Real | Int | Time | Binary;
    LegalString    : string_list;        // For String
    LegalInt       : integer_range_list; // For Int
    LegalReal      : real_range_list;    // For Real
    LegalSize      : int | Unsized;      // For Binary
    AllowedSymbols : string_list;        // For all but String
    IgnoreCase     : On | Off;
    Repeatable     : On | Off;
  }
}
```

Description

A wrapper used in metadata to define the syntax of the RowIdElements of a data wrapper.

Parameters

- *element_id*

  A string used to name the row id element.

  The *element_id* must start with a letter, include only letters, numbers and underscores.

- Type : String | Boolean | Real | Int | Time | Binary;

  A property that defines the type of the RowIdElement. The allowed types are String, Boolean, Real, Int, Time, and Binary. RowIdElements of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the verilog syntax: <size>‘b<binary_digits>, ‘b<binary_digits>, <size>‘h<hexadecimal_digits>, and ‘h<hexadecimal_digits>.

- LegalString : *string_list*;

  A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed list will consider casing or not based on the IgnoreCase property documented below.

- LegalInt : *integer_range_list*;

  A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

- LegalReal : *real_range_list*;

  A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”.

- LegalSize : *int* | Unsized;

  A property that can be used when Type is set to Binary to limit the binary number to a specific size.

- AllowedSymbols : *string_list*;

  A property that can be used when Type is set to anything but String to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property above is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols will consider casing or not based on the IgnoreCase property documented below.

- IgnoreCase : On | Off;

  A property that can be used to make the LegalString and the AllowedSymbols case-insensitive. This option also affects whether casing is ignored when performing the repeatability check described in the following Repeatable property.

- Repeatable : On | Off;

  A property that controls whether a given element_id can be repeated or not within the Data Wrapper. The validation of the repeatability will consider casing or not based on the preceding IgnoreCase property.

Example

The following example defines a data wrapper with RowIdElement which is a arbitrary string meant to represent a clock port name. Each clock port name are only allowed once as specified by the fact that Repeatable is set to Off. Because IgnoreCase is also Off, port names Clk and clk will not be considered as repeated port names.

```
DataWrapper(ClockPeriods) {
  RowIdElement(clock_port) {
    Repeatable : Off;
    Type       : String;
    IgnoreCase : Off;
  }
  Value(period) {
    Type           : Time;
    AllowedSymbols : sync. sync2x;
  }
}
```

Chapter 6
Instrument Connectivity Language (ICL)

Instrument Connectivity Language Syntax

This chapter specifies the syntax of the Instrument Connectivity Language (ICL) of the IEEE P1687 standard draft. The syntax described here is based on the draft version 1.67. Most of the language elements of the IEEE P1687 draft are supported. Currently unsupported ICL language elements or language elements with limited support are clearly marked as follows:

Note

The DefaultLoadValue parameter is currently not supported within the ScanInterface.

The language is introduced not through the formal grammar used in the IEEE P1687 draft, but through a hierarchical description of an ICL Module and its elements. Examples and suggestions for usage are provided for each language element. These elements are divided into language statements; that is, all the elements in the direct body of the ICL Module definition (plus a few more), and parameters. Parameters to an ICL language statement further define the properties of the statement. For example, the ICL language statement ScanRegister has the parameter ResetValue, which defines which value the scan register will assume if the reset signal turns active.

The following sections introduce common features of the language.

Numbers

ICL recognizes unsigned integer numbers in any of the following three number base formats: decimal, hexadecimal, and binary.

Unsized decimal numbers may be composed of a sequence of the digits 0 to 9. If needed, their size will be determined based on context.

Sized numbers are composed of a size constant, followed by an optional white space and a base token (d or D for decimal, h or H for hexadecimal, and b or B for binary), and the digits of the number, expressed in the respective number base. The size constant always expresses the number of binary digits of the sized number, independent of the used base format. For example, the sized numbers 4’b1011, 4’hb and 4’d11 are identical and exactly 4 binary digits wide.

Binary, decimal, and hexadecimal numbers may use their respective common digit symbols (0 and 1 for binary, 0 to 9 for decimal, 0 to 9 and a to f for hexadecimal). These digit symbols are

case insensitive. In addition, binary and hexadecimal numbers may use x or X to denote the unknown digit value.

Padding is applied automatically as necessary if the number of digits of the sized number is less than the size constant requires. For example, assume this comparison:

```
LogicSignal test { dataIn[7:0] == 8'b10 ; }
```

The "==" operator compares two 8-bit (that is, 8 binary digit wide sized numbers). However, only 2 digits "10" are given. Padding is executed based on the following rules: If the left most digit is non-x, then the padding adds as many 0 to the left as necessary. If however the leftmost digit is x, then padding adds as many x to the left as necessary. The above example will therefore be padded to the following:

```
LogicSignal test { dataIn[7:0] == 8'b00000010 ; }
```

The opposite of padding is truncation. Truncation happens if the number of digits of the sized number is larger than the size constant requires. Consequently, excessive digits are removed from the left until the size requirement is matched. However, only occurrences of 0 or x may be removed. Removing any other digit symbol results in an error.

Identifiers

IEEE P1687 differentiates between four identifiers: The scalar identifier, the parameter identifier, the vector identifier, and the pin identifier.

The scalar identifier is used to denote the elements of the ICL netlist such as the ports of a module, a module name or an instance name. The scalar identifier is case sensitive and must start with a letter. Thereafter, the scalar identifier may use letters, numbers, and the underscore symbol. It may not contain any white spaces nor the "[" or "]" symbols (these are used for vector identifiers).

The parameter identifier is used to reference a Parameter or LocalParameter definition. The parameter reference is composed of the "$" symbol and the scalar identifier name of the referenced (local) parameter. For example, if the parameter scalar identifier is userValue, the the parameter reference will be $userValue.

There are two types of vector identifiers: The single index and the range vector identifier. There is no length limit for these identifiers.

A single index vector identifier is composed of a scalar identifier, followed by the "["symbol, an unsigned decimal number, followed by the "]" symbol. Its width is considered to be 1. An example is bus[4], denoting the 4th bit of the scalar identifier bus.

A ranged vector identifier is composed of a scalar identifier, followed by the "[" symbol, a first unsigned decimal number, the ":" symbol, a second unsigned decimal number, and followed by the "]" symbol. An example is:

```
bus[0:4]
```

denoting 5 bits of the scalar identifier bus. Note that the range can either be increasing, for example [0:4], or decreasing, for example [4:0].

Pin identifiers refer to a port name, optionally including an instance path name. The port name is either a scalar, a single index or range index vector identifier. The instance names are all scalar identifiers, and the instance path is composed of these scalar identifiers, separated by the "." symbol. An example is:

```
top.myInstA.myInstB.dataIn[7:0]
```

In this example the identifiers "top", "myInstA" and "myInstB" are all denoting names of instances, whereas dataIn[7:0] is a ranged vector identifier of a port scalar named dataIn.

Limited Identifier Mathematics

Parameter identifiers, single indexes and ranged indexes may use limited mathematical operations: + (addition), - (subtraction), * (multiplication), / (division), and % (modulo). For parameter identifiers, a parameter value can be computed using these operations; for vector identifiers any used unsigned decimal number can be expressed using these operations. In addition, parameter reference may be used. Examples are:

```
Parameter ten = 10 ;
Parameter twenty = 2*$ten ;
bus[$twenty:$ten]
bus[$twenty%2]
bus[$ten-1:0]
```

Concatenations

Under certain conditions, identifiers might be concatenated with other identifiers and/or sized and unsized numbers. The concatenation operator is the "," symbol. A first example is the following:

```
Parameter topBit 1'b1 ;
LogicSignal test { dataInA[3:0], dataInB[3:0] == $topBit, 0, 4'b1111 ; }
```

Observe that the left hand side of the comparator (==) is 8 bits wide. The right hand side has 2 sized numbers of a total width of 5 bits. Therefore the unsized number 0 in the middle will be auto-expanded into 3'b000. It is obvious that such a comparison construct may contain at most one unsigned number. This example shows also the usage of parameter references in lieu of a number.

A concatenation may also include the "~" symbol, denoting a sized, bit-wise, binary inversion. For example: ~4' ha is equivalent to 4'h5.

Interestingly, the "~"symbol can also be used within the concatenation:

```
LogicSignal test { dataInA[3:0], dataInB[3:0] == $topBit, ~0, 4'b1111 ; }
```

Here, the unsized, but inverted 0 is auto-expanded into 4'b1111.

Syntax Conventions

This chapter uses the syntax conventions in Table 6-1 when documenting ICL syntax properties.

Table 6-1. Syntax Conventions for ICL Files

Convention	Example	Usage
Upright	ScanInPort *port_name* ;	An upright font indicates an ICL language element, either a statement or a parameter.
Italic	scan_in : *port_pin_name*;	An italic font indicates a user-supplied value.
Underline	wgl_type : <u>generic</u> | lsi**;**	An underlined item indicates the default value.
|	logic_level : <u>both</u> | high | low;	The vertical bar separates a list of values from which you must choose one. Do not include the bar in the configuration file.
...	port_naming : *port_naming*, ...;	Ellipses indicate a repeatable value. The comment "// repeatable" also indicates a repeatable value.
//	// default: ijtag_so	The double slash indicates the text immediately following is a comment and tells the tool to ignore the text.

Module

Syntax

}
```

Description

The syntax above lists the complete contents (statements) of an ICL module. Not all statements may be used at the same time.

Each ICL statement is explained in detail in the following pages. All statements are hyperlinked from here to the respective statement description, as well as back to this module description.

Parameters

- *module_name*

  The Module statement defines the name of an ICL module. The name of the module must be unique among all loaded modules. To build an ICL design, you use the Instance statement.

NameSpace
UseNameSpace
Instance

Attribute

Example Syntax

```
Module module_name {
  Attribute att_name = att_value ;
}
```

Description

The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool.

Tessent understands several port attributes and pin attributes as defined in this manual. However, Tessent does not have built-in Attributes for all ICL objects. For example, the ScanInterface has no Tessent attribute.

Note that most Tessent attributes are read-only and are automatically generated by the Tessent tool, which also assigns a value to the attribute.

The Attribute statement is not only allowed in Module, but in most ICL objects documented in this Chapter.

Note

In its usage within ICL objects, like modules, ports, scan or data mux, etc., the Attribute statement is always optional.

Parameters

- *att_name* = *att_value*

  An required string and optional “=”symbol and value combination, where *att_name* defines the name of the Attribute, and *att_value*, if present, defines the value of the attribute.

  Within an ICL object where multiple Attribute statements are used, each *att_name* must be unique.

Example 1

The first example shows a very simple usage of assigning a string “true” to an attribute name “is_top”:

```
Module top {
  Attribute is_top = “true” ;
  [...]
}
```

Example 2

The second example shows a Tessent attribute `connection_rule_option` that influences ICL Network Extraction. Please see Influencing ICL Extraction through ICL Module Attributes in the *Tessent IJTAG User’s Manual* for the details of the attribute.

```
DataInPort din {Attribute connection_rule_option = "allowed_tied_high";}
```

ScanInterface

Syntax

```
Module module_name {
  ScanInterface interface_name {
    Attribute att_name = att_value;
    Port port_name;
    DefaultLoadValue load_value;
    Chain chain_name { ... }
  }
}
```

Description

The definition of a set of ports of the module that together perform a scan operation.

The ScanInterface defines a set of ports of the module that together perform a scan operation. A typical example of ports include the shift enable, capture, and update enable ports, together with at least a pair of scan-in and scan-out ports. However, the ScanInterface is applied also to the TAP, since a shift-based interface to or from a module is also defined; that is, a scan interface. See the discussion on *port_names* below, which defines the sets of ports of the four recognized use models of the ScanInterface — the client interface, the host interface, the client TAP interface, and the host TAP interface. A module may have more than one scan interface, in particular several client interfaces or interfaces for different use models. However, only one scan interface may be active at the same time. This means, for example, that a set of scan chains that are supposed to be operated together must all be in the same ScanInterface definition.

For a handoff module, with more than one portfunction of type ScanInPort or ScanOutPort, there must be as many ScanInterface statements as there are scan interfaces in the module. This does not mean, for example, that the number of scan-in and scan-out port pairs defines the number of ScanInterface statements. Since several pairs of scan-in and scan-out ports may belong to the same scan interface, which means they are supposed to be operated simultaneously, the number of ScanInterface statements may be smaller.

The examples below are for simple ScanInterface definitions. Additional examples, especially those for multiple parallel scan chains, are provided in the ScanInterface/Chain section.

Parameters

- *interface_name*

  A required string that defines the name of the scan interface of the module.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent does not have any attributes for the ICL ScanInterface statement.

- Port *port_name*

  A repeatable, optional keyword-string pair that references the name of an existing port of the module. Four use models of a ScanInterface can be distinguished. The port_names for a given ScanInterface must all belong to the same use model.

  - The client interface — Through a client scan interface a module receives all signals necessary to operate a defined set of scan chains. Ports of the following port functions form a client scan interface: at least one pair of ScanInPort and ScanOutPort, one ShiftEnPort and/or at least one SelectPort, and at most one CaptureEnPort, UpdateEnPort, ResetPort, or TCKPort. If the shift enable, capture enable, or update enable ports are not stated and the module has exactly one of each, these ports are implied for the scan interface using the modules set of port functions, or for non-handoff modules, the set or implied set of port functions. If more than one pair of scan-in and scan-out ports belong to the same scan interface, the Chain object must be used. In this case, no port name should reference a scan-in and scan-out port, nor should the DefaultLoadValue be used.

    If a non-handoff module has exactly one client interface, than the ScanInterface statement is not required. The tool assumes a “default” client interface.

  - The host interface — Through a host scan interface a module defines shift operating control signals for another module. Ports of the following port functions form a host scan interface: one ScanInPort and/or one ScanOutPort, one ToShiftEnPort and/or at least one ToSelectPort, and at most one ToCaptureEnPort, ToUpdateEnPort, ToResetPort, or ToTCKPort. Similar to the client interface, if the module has exactly one ToShiftEnPort, ToCaptureEnPort, or ToUpdateEnPort, these ports are assumed for each host scan interface, for which they have not been stated already.

  - The client TAP interface — Through a client TAP interface, the module receives all signals necessary to operate a TAP controller: One of each ScanInPort, ScanOutPort, and TMSPort, and at most one of TRSTPort and TCKPort.

  - The host TAP interface — Through a host TAP interface, the module defines signals for another module’s client TAP interface: One ScanInPort and/or one ScanOutPort, one ToTMSPort, and at least one of ToTRSTPort and ToTCKPort.

- DefaultLoadValue *load_value*

  An optional keyword-string pair that defines the value to be loaded into the single scan chain defined by a pair port names of portfunction type ScanInPort and ScanOutPort of a black-box module. This keyword is currently not supported within the ScanInterface.

- Chain *chain_name*

  A repeatable, optional keyword-string pair that declares the name of a scan chain of the module. All chain names must be unique within a ScanInterface. If the ScanInterface has only one ScanInPort/ScanOutPort pair, than Chain object is not required.

Example 1

The following example shows three equivalent description of an ICL module with a single scan-in / scan-out client scan interface. This is not a complete list, other variations are possible. Note that for the module tdr4_1, no ScanInterface statement is given. It is not necessary, since the module has exactly one client scan interface. However, you may provide a ScanInterface as shown for modules tdr4_2, and tdr4_3.

```
Module tdr4_1 {
   ScanInPort       si;
   ScanOutPort      so       { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
   }
}

Module tdr4_2 {
   ScanInPort       si;
   ScanOutPort      so       { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanInterface interface1 {
     Port en ;
     Port si; Port so;
   }

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
   }
}

Module tdr4_3 {
   ScanInPort       si;
   ScanOutPort      so       { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanInterface interface2 {
     Port se ;
     Chain chain1 {
        Port si; Port so;
     }
```

```
      }

      ScanRegister R[7:0] {
         ScanInSource     si;
         ResetValue       8'b0 ;
      }
   }
```

Example 2

The next example shows the port functions and both the client and host TAP interfaces of a typical TAP controller module.

```
   Module tap {
      TCKPort         tck;
      ScanInPort      tdi;
      ScanOutPort     tdo       {  Source IRMux; }
      TMSPort         tms;
      TRSTPort        trst;
      ToSelectPort    tdrEn     {  Source sel;  }
      ScanInPort      fromTdr;
      ToSelectPort    tapEn     {  Source IR[2]; }
      ToCaptureEnPort tce;
      ToShiftEnPort   tse;
      ToUpdateEnPort  tue;

      ScanInterface clientTAP {
        Port tdi; Port tdo;
        Port tms; Port trst;
      }
      ScanInterface hostTAP   {
        Port fromTdr1; Port tdrEn1;
        Port tce; Port tse; Port tue;
      }
      [...]
   }
```

Example 3

The next example shows an example implementation of a SIB (Segment Insertion Bit) module. This module implements a scan chain switch by selecting either of two scan input ports. The module also generates an outgoing enable signal that is correlated to the second scan-in port.

```
   Module sib {
      ScanInPort       si;
      ScanOutPort      so   { Source SIB; }
      ShiftEnPort      se;
      CaptureEnPort    ce;
      UpdateEnPort     ue;
      SelectPort       en;
      TCKPort          tck;
      ScanInPort       fso;
      ToSelectPort     ten  { Source And; }

      ScanInterface client {
        Port si; Port so;
        Port se; Port ce; Port ue; Port en;
      }
```

```
      ScanInterface host   {
        Port fso; Port ten;
      }

      ScanRegister SIB {
         ResetValue     1'b0;
         ScanInSource   Mux;
      }

      ScanMux Mux SelectedBy SIB {
         1'b0 : si;
         1'b1 : fso;
      }

      LogicSignal And { en,SIB == 2'b11;  }
   }
```

Chain

Syntax

```
ScanInterface interface_name {
  Chain chain_name {
    Attribute att_name = att_value;
    Port port_name;
    DefaultLoadValue load_value;
  }
}
```

Description

The Chain statement defines the name of a scan chain within a ScanInterface.

This statement does not create a scan register in the sense of the ScanRegister statement. Here it is only a declaration which ScanInPort and ScanOutPort of the module will be operated together with the control signals of the ScanInterface. There can be more than one Chain statement in a ScanInterface. In this case, each scan chain name must be unique.

Parameters

- Chain *chain_name*

  A repeatable, required keyword-string pair that defines the name of a scan chain within a given ScanInterface. There can be more than one scan chain in any given ScanInterface. However, the names of the scan chains within a ScanInterface must all be unique.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent does not have any built-in attributes for the ScanInterface/Chain statement.

- Port *port_name*

  A required keyword-string pair, with the port_name referencing a ScanInPort or ScanOutPort port of the module. Within each Chain statement, there are exactly two Port statements, one referencing the scan-in port, and the other referencing the scan-out port.

- DefaultLoadValue *load_value*

  An optional keyword-string pair that defines the value to be loaded into the single scan chain defined by a pair port names of portfunction type ScanInPort and ScanOutPort of a black-box module. This keyword is currently not supported within the Chain object.

Example 1

The following example shows a module with two client ScanInterfaces, each operating two scan chains.

```
Module chip1 {
   ScanInPort  siA1 ;
```

```
      ScanInPort  siA2 ;
      ScanOutPort soA1 { Source blockA.so1 ; }
      ScanOutPort soA2 { Source blockA.so2 ; }

      ScanInPort  siB1 ;
      ScanInPort  siB2 ;
      ScanOutPort soB1 { Source blockB.so1 ; }
      ScanOutPort soB2 { Source blockB.so2 ; }

      ShiftEnPort   se1 ;
      CaptureEnPort ce1 ;
      UpdateEnPort  ue1 ;

      ShiftEnPort   se2 ;
      CaptureEnPort ce2 ;
      UpdateEnPort  ue2 ;

      TCKPort tck ;

      ScanInterface cA12 {
         Port se1; Port ce1; Port ue1;
         Chain c1 { Port siA1; Port soA1 ; }
         Chain c2 { Port siA2; Port soA2 ; }
      }

      ScanInterface cB12 {
         Port se2; Port ce2; Port ue2;
         Chain c1 { Port siB1; Port soB1 ; }
         Chain c2 { Port siB2; Port soB2 ; }
      }
      [...]
   }
```

Example 2

In this variation of Example 1 above, the ShiftEnPort, CaptureEnPort, and UpdateEnPort ports are shared among both ScanInterface. The selection between the two interfaces is accomplished through the two SelectPort sel1 and sel2, respectively.

```
   Module chip2 {
      ScanInPort  siA1 ;
      ScanInPort  siA2 ;
      ScanOutPort soA1 { Source blockA.so1 ; }
      ScanOutPort soA2 { Source blockA.so2 ; }

      ScanInPort  siB1 ;
      ScanInPort  siB2 ;
      ScanOutPort soB1 { Source blockB.so1 ; }
      ScanOutPort soB2 { Source blockB.so2 ; }

      SelectPort   selA ;
      SelectPort   selB ;

      ShiftEnPort   se ;
      CaptureEnPort ce ;
      UpdateEnPort  ue ;

      TCKPort tck ;
```

```
      ScanInterface cA12 {
         Port selA;
         Chain c1 { Port siA1; Port soA1 ; }
         Chain c2 { Port siA2; Port soA2 ; }
      }

      ScanInterface cB12 {
         Port selB;
         Chain c1 { Port siB1; Port soB1 ; }
         Chain c2 { Port siB2; Port soB2 ; }
      }
      [...]
   }
```

Example 3

This example is another variation of Example 1. The difference is that all ports are busses and not individual ports as in Example 1. The operation of the modules is identical.

```
   Module chip3 {
      ScanInPort  si[3:0] ;
      ScanOutPort so[3:0] { Source blockA.so1, blockA.so2,
                                   blockB.so1, blockB.so2 ;
                          }

      ShiftEnPort   se[1:0] ;
      CaptureEnPort ce[1:0] ;
      UpdateEnPort  ue[1:0] ;

      TCKPort tck ;

      ScanInterface cA12 {
         Port se[0]; Port ce[0]; Port ue[0];
         Chain c1 { Port si[0]; Port so[0] ; }
         Chain c2 { Port si[1]; Port so[1] ; }
      }

      ScanInterface cB12 {
         Port se[1] ; Port ce[1]; Port ue[1];
         Chain c1 { Port si[2]; Port so[2] ; }
         Chain c2 { Port si[3]; Port so[3] ; }
      }
      [...]
   }
```

ScanInterface

ScanRegister

ScanInPort

Syntax

```
Module module_name {
  ScanInPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of a scan input port of a Module.

A module may have zero or more scan-in ports. However, if a module has at least one ScanOutPort defined, then there must be at least one ScanInPort.

If a module has exactly one ScanInPort, than the module may also have a ScanInterface defined. However, if a module has more than one ScanInPort, than there must be at least one ScanInterface definition.

The scan-in port is used to execute a serial write (that is, not a parallel write operation). If a parallel write is to be done, use the DataInPort port function instead.

Parameters

- *port_name*

  A required string that identifies the name of a scan-in port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no ScanInterface is required. The scan-in port is named “si”. Observe that the port name is reused in the body of the ScanRegister R[7:0] declaration. There, it declares that the scan register will receive its scan data from the object named “si”, which happens to be the ScanInPort of the Module.

```
Module tdr2 {
```

```
      ScanInPort       si;
      ScanOutPort      so  { Source R[0]; }
      ShiftEnPort      se;
      SelectPort       en;
      CaptureEnPort    ce;
      UpdateEnPort     ue;
      TCKPort          tck;

      ScanRegister R[7:0] {
         ScanInSource     si;
         ResetValue       8'b0 ;
         DefaultLoadValue 8'b0 ;
      }
   }
```

DataInPort

ShiftEnPort

Syntax

```
Module module_name {
  ShiftEnPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the shift enable port of a Module's client ScanInterface.

This port is used to enable the shift operation into a module's ScanRegister elements. A module may have zero or more shift enable ports. For an internal module; that is, not a hand-off module, a single shift enable port is implied if there are scan in/out ports in the module. In this case, a ShiftEnPort need not be declared. The ShiftEnPort must be declared if:

- The module is a hand-off module.
- There is more than one shift enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The shift enable signal is an active high signal. A ShiftEnPort of an instance is sourced by a ToShiftEnPort. A ScanRegister object is expected to hold its scan data, as long as the shift enable port is low, independently on the number of clock cycles.

Parameters

- *port_name*

  A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ShiftEnPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name = att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client ScanInterface is required. The shift enable port is named "se". Observe that

the body of the Module does not further use the shift enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the ScanInterface to learn how you can use multiple scan chains, potentially with multiple shift enable signals.

```
Module tdr2 {

   ScanInPort       si;
   ScanOutPort      so  { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
      DefaultLoadValue 8'b0 ;
   }
}
```

ScanOutPort
ScanInterface

CaptureEnPort

Syntax

```
Module module_name {
  CaptureEnPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the capture enable port of a Module's client ScanInterface.

This port is used to control the capture operation of a module's ScanRegister elements. A module may have zero or more capture enable ports. For an internal module; that is, not a hand-off module, a single capture enable port is implied if there are scan in/out ports in the module. In this case, a CaptureEnPort need not be declared. The CaputureEnPort must be declared if:

- The module is a hand-off module.
- There is more than one capture enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The capture enable signal is an active high signal. A CaptureEnPort of an instance is sourced by a ToCaptureEnPort or by a DataOutPort, that in its fanin resolves to a single ToCaptureEnPort. If the source of the capture enable port resolves to 0, the capture enable pulse is assumed to be suppressed.

Note

The suppressing of the enable signal described above is currently not supported in Tessent.

Parameters

- *port_name*

  A required string that identifies the name of a capture enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL CaptureEnPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client ScanInterface is required. The capture enable port is named “ce”. Observe that the body of the Module does not further use the capture enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the ScanInterface to learn how you can use multiple scan chains, potentially with multiple capture enable signals.

```
Module tdr2 {

   ScanInPort       si;
   ScanOutPort      so  { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
      DefaultLoadValue 8'b0 ;
   }
}
```

UpdateEnPort

Syntax

```
Module module_name {
  UpdateEnPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the update enable port of a Module's client ScanInterface.

This port is used to control the update operation of a module's ScanRegister elements. A module may have zero or more capture enable ports. A module may have zero or more update enable ports. For an internal module; that is, not a hand-off module, a single update enable port is implied if there are scan in/out ports in the module. In this case, an UpdateEnPort need not be declared. The UpdateEnPort must be declared if:

- The module is a hand-off module.
- There is more than one update enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The update enable signal is an active high signal. An UpdateEnPort of an instance is sourced by a ToUpdateEnPort or by a DataOutPort, that in its fanin resolves to a single ToUpdateEnPort. If the source of the update enable port resolves to 0, the update enable pulse is assumed to be suppressed.

Note

The suppressing of the enable signal described above is currently not supported in Tessent.

Parameters

- *port_name*

  A required string that identifies the name of an update enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL UpdateEnPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as

defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client ScanInterface is required. The update enable port is named “ue”. Observe that the body of the Module does not further use the update enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the ScanInterface to learn how you can use multiple scan chains, potentially with multiple update enable signals.

```
Module tdr2 {

   ScanInPort       si;
   ScanOutPort      so  { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
      DefaultLoadValue 8'b0 ;
   }
}
```

DataInPort

Syntax

```
Module module_name {
  DataInPort port_name {
    RefEnum enum_name ;
    DefaultLoadValue default_load_value;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the data in port of a Module.

A module may have zero or more data in ports. The number and bus-width of all declared data in ports is not correlated to the number and bus-width of any DataOutPort.

A data in port is used to execute a parallel write (that is, not a scan operation), to ports of the module. For a scan operation, use the ScanInPort port function instead. If parallel writes to ports of the module are allowed, the DataInPort function(s) must be declared for the module. If a module does not have DataInPort port functions, no parallel data write is allowed. Certain additional restrictions apply as explained next.

There should be at most one RefEnum per DataInPort, and the widths of the data within the referenced enumeration table should match the width of the data in port.

If a data in port is used to select a scan path, for example, as the select of a ScanMux, it may not be target of a write operation. This ensures that the scan selection remains under control of the software application.

If a data in port is connected to an Instance or DataRegister with an AddressValue statement, all data in ports are concatenated in the order of declaration until the required data width is achieved. See the discussion of AddressValue for further explanation and an example.

Parameters

- *port_name*

  A required string that identifies the name of a data in port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL DataInPort of the module that is also used for the respective ports of the module in the design.

- RefEnum *enum_name*

  An optional keyword-string pair that references the name of an Enum table. Using the enumeration table, the writing to the data in port can use synonyms listed in the table, instead of bit strings. It must be understood that the enumeration table is not necessarily a

complete list. It is still allowed to write to the data in ports any value, including those not listed in the enumeration table. A DataInPort may have at most one RefEnum statement.

- DefaultLoadValue *default_load_value*

  An optional keyword-string pair that identifies the value that each DataIn port will assume if no user-defined value had been written to it beforehand and other bits of the Ports needs to be written to. If used, the width of *default_load_value* must match the width of the port.

  For DataInPorts on the current design, the tool will automatically force those DataInPorts to the specified *default_load_value* at the beginnign of the pattern. There is one exception to this behavior. If the DataInPort is declared as an inout port in the design module having the same name as the top level ICL module, the port is driven to Z at the beginning of the pattern and will remain Z until the port is the target of an explicit iWrite command or its value is needed to justify other iRead or iWrite commands.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example 1

The following example shows an ICL module definition with only DataInPort, DataOutPort, and a ClockPort port functions. This module does not include any scan interface. Its only way of data IO is through the parallel data port in[7:0] and out[7:0]. Observe that the body of the module is empty, not containing any other ICL objects, like DataRegister, or LogicSignal.

```
Module instrument {
   DataInPort  in[7:0];
   DataOutPort out[7:0];
   ClockPort   clk;
}
```

Example 2

The following example shows an ICL module definition with both a parallel data input/output and a scan interface (implicitly defined, since there is only one scan-in / scan-out pair). Observe how the data in port is used inside the ScanRegister. It is declared as the source of the capture values of the scan register, which means that the scan register will capture the value from the data in ports fq on the positive edge of the CaptureEnPort ce, under the condition that the SelectPort en is also high. Finally, observe the usage of the RefEnum and Enum statements.

```
Module tdr_ref {
   ScanInPort       si;
   ScanOutPort      so       {  Source R[0];   }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
```

```
    TCKPort          tck;
    DataInPort       fq[7:0]  { RefEnum OptionalValues; }
    DataOutPort      td[7:0]  { Source R[7:0]; RefEnum OptionalValues; }

    ScanRegister R[7:0] {
       CaptureSource fq[7:0];
       ScanInSource  si;
       RefEnum       OptionalValues ;
    }

    Enum OptionalValues {
        reset = 8'b0 ;
        set   = 8'b11111111 ;
        chain = 8'b11001100 ;
        green = 8'hee ;
        blue  = 8'd198 ;
    }
}
```

Example 3

The following example shows how a data input port can be used to select a scan path. In such a case, the data input port falls under the control of the Tessent, which will determine the necessary data in values to fulfill any read or write requests to the scan chains.

```
Module msel {
  ScanOutPort so { Source smux; }
  DataInPort  dataSel;
  ScanMux smux SelectedBy dataSel {
    1’b0 : tdr0[0];
    1'b1 : tdr1[0];
  }
  [...]
}
```

ScanInPort
ScanOutPort
Enum

SelectPort

Syntax

```
Module module_name {
  SelectPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the select input port of a Module's client ScanInterface.

A module may have zero or more select ports. It is used to enable a scan interface of a module. When the select port is active (high), the scan interface is active. However, if the select port is inactive (low), the scan interface will not respond to any other control signal defined for this scan interface. The SelectPort statement for a non-handoff module is optional and implied of the module has a scan interface. The SelectPort is only required if the port is part of the ScanInterface statement. A SelectPort which is not part of a scan interface and which is not part of the scan network configuration logic is equivalent to a DataInPort.

Parameters

- *port_name*

  A required string that identifies the name of a select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL SelectPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

In this example, the ShiftEnPort, CaptureEnPort, and UpdateEnPort ports are shared among both ScanInterface. The selection between the two interfaces is accomplished through the two SelectPort sel1 and sel2, respectively.

```
Module chip2 {
   ScanInPort  siA1 ;
   ScanInPort  siA2 ;
   ScanOutPort soA1 { Source blockA.so1 ; }
```

```
      ScanOutPort soA2 { Source blockA.so2 ; }

      ScanInPort  siB1 ;
      ScanInPort  siB2 ;
      ScanOutPort soB1 { Source blockB.so1 ; }
      ScanOutPort soB2 { Source blockB.so2 ; }

      SelectPort   selA ;
      SelectPort   selB ;

      ShiftEnPort   se ;
      CaptureEnPort ce ;
      UpdateEnPort  ue ;

      TCKPort tck ;

      ScanInterface cA12 {
         Port selA;
         Chain c1 { Port siA1; Port soA1 ; }
         Chain c2 { Port siA2; Port soA2 ; }
      }

      ScanInterface cB12 {
         Port selB;
         Chain c1 { Port siB1; Port soB1 ; }
         Chain c2 { Port siB2; Port soB2 ; }
      }
      [...]
   }
```

ResetPort

Syntax

```
Module module_name {
  ResetPort port_name {
    Attribute att_name = att_value ;
    ActivePolarity 0 | 1;
  }
}
```

Description

A port function that declares the name of the reset input port of a Module's client ScanInterface.

You have the option to chose the active polarity of the port. The active polarity is determined for you, if the port is connected to a data port of another instance, or to a TRSTPort.

Parameters

- *port_name*

  A required string that identifies the name of a reset port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ResetPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- *ActivePolarity 0|1*

  An optional keyword-value pair, that defines if the reset port of the module is considered active low (value = 0), or active high (value =1). If the ActivePolarity statement is not given, the active polarity of the reset port is assumed to be high.

  The reset port may have an additional data signal in its fanin. (Consider the reset signal of the module being the OR of the reset signal of the parent module and the data signal). In this case the reset port is considered active if either data signal is high (1) or the parents reset signal is active. An additional condition is that there must be a unique reset signal in the parent module.

Note

The functionality described in the last paragraph is called a local reset. It is currently not supported in Tessent.

Related Topics

ScanOutPort

ScanInterface

TMSPort

Syntax

```
Module module_name {
  TMSPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the TMS input port of a Module's client TAP ScanInterface.

If a module has a client TAP interface, the TMSPort declaration may not be omitted. If the module has a ToIRSelectPort, the module must also have exactly one TMSPort.

IEEE P1687 supports top level TAPs, as well as any number of embedded TAP controllers.

Parameters

- *port_name*

  A required string that identifies the name of the TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias

  It is recommended to use a port name for the ICL TMSPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IEEE P1687 has built-in the knowledge of a TAP's state machine.

```
Module tap {
   TCKPort          tck;
   ScanInPort       tdi;
   ScanOutPort      tdo        {  Source IRMux; }
   TMSPort          tms;
   TRSTPort         trst;
   ToSelectPort     tdrEn1     {  Source sel1;  }
```

```
    ScanInPort      fromTdr1;
    ToSelectPort    tapEn1    {  Source IR[2]; }
    ToCaptureEnPort tce;
    ToShiftEnPort   tse;
    ToUpdateEnPort  tue;

    ScanInterface clientTAP {
      Port tdi; Port tdo;

TCKPort

Syntax

```
Module module_name {
  TCKPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the test clock (TCK) input port of a Module.

The declaration of the TCKPort is optional for an internal module (that is, not for a hand-off module), even if the module contains scan registers. In this case, the test clock is implicitly assumed.

A module may have more than one TCKPort statement. In this case, all declared test clocks will be considered equivalent and with the same polarity.

Non test clock ports are defined through the ClockPort statement.

Note that IEEE P1687 has no means of defining the actual speed of a test clock. This is left to the software implementing the standard. In Tessent, you can use the add_clocks command to define clock properties, like the period or the off-value.

Parameters

- *port_name*

  A required string that identifies the name of the test clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotScanGroup, OneHotDataGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL TCKPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ClockPort

Syntax

```
Module module_name {
  ClockPort port_name {
    Attribute att_name = att_value ;
    DifferentialInvOf other_clock_port_name ;
  }
}
```

Description

A port function that declares the name of a functional clock input port of a Module (that is, a clock that is not a test clock).

A test clock is defined through the TCKPort statement. A module may have zero or more clock ports.

Note that IEEE P1687 has no means of defining the actual speed of a functional clock. This is left to the software implementing the standard. In Tessent, you can use the add_clocks command to define clock properties, like the period, or if the clock is synchronous or asynchronous to the test clock. Inside of ICL, only the ToClockPort statement can be used to model an oscillator-like behavior.

Parameters

- *port_name*

  A required string that identifies the name of a clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ClockPort of the module that is also used for the respective ports of the module in the design.

- DifferentialInvOf *other_clock_port_name*

  An optional keyword-string pair. Differential functional clocks are declared through the DifferentialInvOf keyword. The *other_clock_port_name* string references another ClockPort *port_name* of the same module.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example declares one test clock and two functional, non-test clocks, an ordinary one and a differential one, the latter of which consists of two clock pins “pdiff” and “ndiff”.

```
Module top {
   TCKPort tck;
   ClockPort sclk;
   ClockPort pdiff;
   ClockPort ndiff { DifferentialInvOf pdiff ; }
}
```

Related Topics

TCKPort

TRSTPort

Syntax

```
Module module_name {
  TRSTPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of a TAP reset input port of a Module's client TAP ScanInterface. The active polarity of the port is low.

Especially for embedded TAP controllers, it becomes important to gate-off the global TRST signal. This is accomplished by assuming an AND gate between a data signal and global, unique TRST signal. Note that if the TRST port has a data signal in its fanin in addition to the unique TRST signal, the module's TRST signal is assumed suppressed if the data signal evaluates to 0.

Note

The functionality described in the last paragraph is called a local reset. It is currently not supported in Tessent.

Parameters

- *port_name*

  A required string that identifies the name of the TRST port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL TRSTPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ScanInterface

AddressPort

Syntax

```
Module module_name {
  AddressPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of an address input port of a Module. It is used if the module contains addressable instances or data registers.

This port serves as the address of the addressable instances and data registers.

Parameters

- *port_name*

  A required string that identifies the name of an address port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL AddressPort of the module that is also used for the respective ports of the module in the design.

  The source of the address port name signal may only be an address port of the parent module, or scan register bits of a ScanRegister statement. In both cases, this connection must be direct, and may not include any logic signals.

  If a module has more than one AddressPort, the address comparison with logic signals of the module implicitly concatenates all address port signals in order of declaration (top to bottom).

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

WriteEnPort

Syntax

```
Module module_name {
  WriteEnPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the write enable input port of a Module. It is used if the module contains addressable instances or data registers.

This port serves as the write enable to the addressable instance and data registers.

Parameters

- *port_name*

  A required string that identifies the name of a write enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the module in the design.

  The source of the write enable port name signal may only be a write enable port of the parent module, or scan register bits of a ScanRegister statement. In both cases, this connection must be direct, and may not include any logic signals.

  A module may have at most one WriteEnPort statement. A module must have a WriteEnPort statement, if the module contains writable, addressable data registers or writable, addressable instances.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Instance
ReadEnPort
DataRegister

ReadEnPort

Syntax

```
Module module_name {
  ReadEnPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the read enable input port of a Module. It is used if the module contains addressable instances or data registers.

This port serves as the read enable to the addressable instance and data registers.

A read operation is executed in two steps. At first the ReadEnPort must be activated (high) and the address must be supplied (AddressPort). In the second step, the capture is executed and the data is being read. During this second step the ReadEnPort is automatically deactivated (low) by means of an automatic iApplyEndState property (see the Alias statement).

Parameters

- *port_name*

  A required string that identifies the name of a read enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the module in the design.

  The source of the read enable port name signal may only be a read enable port of the parent module, or scan register bits of a ScanRegister statement. In both cases, this connection must be direct, and may not include any logic signals.

  A module may have at most one ReadEnPort statement. A module must have a ReadEnPort statement, if the module contains readable, addressable data registers or readable, addressable instances.

  A read enable port is assumed to have an automatic iApplyEndState property. See the Alias statement to learn more about iApplyEndState.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ScanOutPort

Syntax

Syntax 1

```
Module module_name {
  ScanOutPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ScanOutPort port_name {
    Source source_name ;
    Enable enable_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of a scan-out port of a Module.

A module may have zero or more scan-out ports. However, if a module has at least one ScanInPort defined, then there must be at least one ScanOutPort.

The scan-out port is used to execute a serial read (that is, not a parallel read operation). For a parallel read, use the DataOutPort port function instead.

If none of the parameters Source, Enable, or Attribute are used, you must use Syntax 1. However, in this case, the scan chain is broken at the ScanOutPort. Retargeting cannot use this port, and if no other solution can be found, reading and writing from the broken scan segment will result in an error during PDL command retargeting.

Parameters

- *port_name*

  A required string that identifies the name of a scan-out port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ScanOutPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  A keyword-string pair that identifies the source of the scan-out data, like a ScanRegister or a ScanOutPort of another module instance. A ScanOutPort may have at most one Source statement. The Source statement is not needed for black box modules, which are currently not supported by Tessent. If the source_name references a ScanRegister, it should reference the right most bit of the register. Further, the width of the Source must match the width of the ScanOutPort.

- Enable *enable_name*

  A keyword-string pair that identifies the enable signal of the scan-out port. The enable signal must become active in order to connect the scan-out port with the scan source. The activation and deactivation of the enable signal is taken care of by Tessent. Please see the OneHotScanGroup to learn more about the usage of the enable signal. A ScanOutPort may have at most one Enable statement.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows the usage of the ScanOutPort and its Source statement. Observe that the width of the scan-out port is 2, hence the concatenation of the right most bits of both scan registers. Please see the discussion and examples of the OneHotScanGroup to learn more about the usage of the ScanOutPort's enable signal.

```
Module tdr2x {
   ScanInPort       si[1:0];
   ScanOutPort      so[1:0] { Source R0[0],R1[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanInterface chain2x {
     Port se ;
     Chain c0 { Port si[0]; Port so[0]; }
     Chain c1 { Port si[1]; Port so[1]; }
   }

   ScanRegister R0[9:0] {
      ScanInSource     si[0];
      ResetValue       10'b0 ;
   }

   ScanRegister R1[4:0] {
      ScanInSource     si[1];
      ResetValue       5'b0 ;
   }
}
```

DataOutPort

Syntax

Syntax 1

```
Module module_name {
  DataOutPort port_name ;
}
```

Syntax 2

```
Module module_name {
  DataOutPort port_name {
    Source source_name ;
    Enable enable_name ;
    RefEnum enum_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the data out port of a Module.

A module may have zero or more data out ports. The number and bus-width of all declared data out ports is not correlated to the number and bus-width of any DataInPort.

A data out port is used to execute a parallel read (that is, not a scan operation) to ports of the module or to readable objects inside the module, like DataRegister. If data is to be scanned-out, use the ScanOutPort port function instead. If a parallel read from ports or objects of the module is to be allowed, the DataOutPort function(s) must be declared for the module. If a module does not have DataOutPort port functions, no parallel data read is allowed. Certain additional restrictions apply as explained next.

If the data output port signal has SelectPort or ToSelectPort, which is part of an ScanInterface in its fanin, then it may not be target of an iWrite or iRead operation. This ensures that the scan selection remains under control of the software application.

If a data out port is connected to an Instance or DataRegister with an AddressValue statement, all data out ports are concatenated in the order of declaration until the required data width is achieved. See the discussion of AddressValue for further explanation and an example.

If none of the parameters Source, Enable, Attribute, or RefEnum are used, you must use Syntax 1. However, in this case, the data connection is broken at the DataOutPort. Retargeting cannot use this port, and if no other solution can be found, reading and writing from the broken data connection will result in an error during PDL command retargeting.

Parameters

- *port_name*

  A required string that identifies the name of a data out port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any

of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

It is recommended to use a port name for the ICL DataOutPort of the module that is also used for the respective ports of the module in the design.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the parallel output data, like a DataRegister or a DataOutPort of another module instance. A DataOutPort may have at most one Source statement. Further, the width of the Source must match the width of the DataOutPort.

- Enable *enable_name*

  An optional keyword-string pair that identifies the enable signal of the data out port. The enable signal must become active in order to connect the data output port with the data source. The activation and deactivation of the enable signal is taken care of by Tessent. Please see the to learn more about the usage of the enable signal. A DataOutPort may have at most one Enable statement.

- RefEnum *enum_name*

  An optional keyword-string pair that references the name of an Related Topics table. Using the enumeration table, the writing to the data in port can use synonyms listed in the table, instead of bit strings. It must be understood that the enumeration table is not necessarily a complete list. It is still allowed to write to the data in ports any value, including those not listed in the enumeration table. A DataOutPort may have at most one RefEnum statement.

- Attribute *att_name = att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example shows an ICL module definition with both a parallel data input/output and a scan interface (implicitly defined, since there is only one scan-in / scan-out pair). Observe how the data in port is used inside the ScanRegister. It is declared as the source of the capture values of the scan register, which means that the scan register will capture the value from the data in ports fq on the positive edge of the CaptureEnPort ce, under the condition that the SelectPort en is also high. Finally, observe the usage of the RefEnum and Related Topics statements.

```
Module tdr_ref {
   ScanInPort       si;
   ScanOutPort      so      {  Source R[0];   }
   ShiftEnPort      se;
   SelectPort       en;
```

```
        CaptureEnPort    ce;
        UpdateEnPort     ue;
        TCKPort          tck;
        DataInPort       fq[7:0]  { RefEnum OptionalValues; }
        DataOutPort      td[7:0]  { Source R[7:0]; RefEnum OptionalValues; }

        ScanRegister R[7:0] {
           CaptureSource fq[7:0];
           ScanInSource  si;
           RefEnum       OptionalValues ;
        }

        Enum OptionalValues {
            reset = 8'b0 ;
            set   = 8'b11111111 ;
            chain = 8'b11001100 ;
            green = 8'hee ;
            blue  = 8'd198 ;
        }
    }
```

ToShiftEnPort

Syntax

Syntax 1

```
Module module_name {
  ToShiftEnPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToShiftEnPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-shift enable port of a Module's host ScanInterface.

This port is used to enable the shift operation of another module's ScanRegister elements. It is an active high output signal. A module may have zero or more to-shift enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToShiftEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-shift enable signal. A ToShiftEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToShiftEnPort.

  A to-shift enable signal pointing to a shift enable signal may evaluate to a constant 0 or a constant 1. If it evaluates to a constant 0, the scan network controlled by the to-shift enable signal is considered disabled. No read or write operation into this scan chain segment may occur. If it evaluates to a constant 1, it is considered an error.

Note

The Source statement is currently not supported.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IEEE P1687 has built-in the knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

```
Module tap {
   TCKPort         tck;

ToCaptureEnPort

Syntax

Syntax 1

```
Module module_name {
  ToCaptureEnPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToCaptureEnPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-capture enable output port of a Module's host ScanInterface.

This port is used to trigger the capture operation of another module's ScanRegister elements. It is an active high output signal. A module may have zero or more to-update enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToCaptureEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-capture enable signal. A ToCaptureEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToCaptureEnPort.

  The Source may point to a data signal. The to-capture enable signal is considered inactive, if the data signal resolves to 0. Conversely, if the data signal must be resolved to 1 by the tool, to enable the to-capture enable signal. In either case, Tessent will automatically compute the appropriate data signal values for the requested read or write operation to the dependent module's scan network. In addition, if Source points to a data signal, the module may have at most one capture enable signal. You can think of this as an AND gate with one input being the data signal, and the other being the capture enable signal.

Note
The Source statement is currently not supported.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example 1

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IEEE P1687 has built-in the knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

```
Module tap {
   TCKPort         tck;
   ScanInPort      tdi;
   ScanOutPort     tdo       {  Source IRMux; }
   TMSPort         tms;
   TRSTPort        trst;
   ToSelectPort    tdrEn1    {  Source sel1;  }
   ScanInPort      fromTdr1;
   ToSelectPort    tapEn1    {  Source IR[2]; }
   ToCaptureEnPort tce;
   ToShiftEnPort   tse;
   ToUpdateEnPort  tue;

   ScanInterface clientTAP {
     Port tdi; Port tdo;
     Port tms; Port trst;
   }
   ScanInterface hostTAP   {
     Port fromTdr1; Port tdrEn1;
     Port tce; Port tse; Port tue;
   }

   Instance fsm_i Of fsm  {
      InputPort tck  = tck;
      InputPort tms  = tms;
      InputPort trst = trst;
    }

   ScanRegister IR[2:0] {
      CaptureSource  3'b001;
      ResetValue     3'b000;
      ScanInSource   tdi;
   }

   ScanRegister bypass {
```

```
         CaptureSource  1'b0;
         ScanInSource   tdi;
      }

      ScanMux IRMux SelectedBy fsm_i.irSel {
         1'b0 : DRMux;
         1'b1 : IR[0];
      }

      ScanMux DRMux SelectedBy IR[2:0] {
         3'bx00 : bypass;
         3'bx01 : fromTdr1;
      }

      LogicSignal sel1 {  IR[2:0] == 3'bx01; }
   }

   Module fsm {
      TCKPort        tck;
      TMSPort        tms;
      TRSTPort       trst;
      ToIRSelectPort irSel;
      ToResetPort    tlr;
   }

ToUpdateEnPort

Syntax

Syntax 1

```
Module module_name {
  ToUpdateEnPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToUpdateEnPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-update enable port of a Module's host ScanInterface.

This port is used to trigger the update operation of another module's ScanRegister elements. It is an active high output signal. A module may have zero or more to-update enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToUpdateEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-update enable signal. A ToUpdateEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToUpdateEnPort.

  The Source may point to a data signal. The to-update enable signal is considered inactive, if the data signal resolves to 0. Conversely, if the data signal must be resolved to 1 by the tool, to enable the to-update enable signal. In either case, Tessent will automatically compute the appropriate data signal values for the requested read or write operation to the dependent module's scan network. In addition, if Source points to a data signal, the module may have at most one update enable signal. You can think of this as an AND gate with one input being the data signal, and the other being the update enable signal.

Note
The Source statement is currently not supported.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example 1

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IEEE P1687 has built-in the knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

```
Module tap {
   TCKPort         tck;
   ScanInPort      tdi;
   ScanOutPort     tdo       {  Source IRMux; }
   TMSPort         tms;
   TRSTPort        trst;
   ToSelectPort    tdrEn1    {  Source sel1;  }
   ScanInPort      fromTdr1;
   ToSelectPort    tapEn1    {  Source IR[2]; }
   ToCaptureEnPort tce;
   ToShiftEnPort   tse;
   ToUpdateEnPort  tue;

   ScanInterface clientTAP {
     Port tdi; Port tdo;
     Port tms; Port trst;
   }
   ScanInterface hostTAP   {
     Port fromTdr1; Port tdrEn1;
     Port tce; Port tse; Port tue;
   }

   Instance fsm_i Of fsm  {
      InputPort tck  = tck;
      InputPort tms  = tms;
      InputPort trst = trst;
    }

   ScanRegister IR[2:0] {
      CaptureSource  3'b001;
      ResetValue     3'b000;
      ScanInSource   tdi;
   }

   ScanRegister bypass {
```

```
         CaptureSource  1'b0;
         ScanInSource   tdi;
      }

      ScanMux IRMux SelectedBy fsm_i.irSel {
         1'b0 : DRMux;
         1'b1 : IR[0];
      }

      ScanMux DRMux SelectedBy IR[2:0] {
         3'bx00 : bypass;
         3'bx01 : fromTdr1;
      }

      LogicSignal sel1 {  IR[2:0] == 3'bx01; }
   }

   Module fsm {
      TCKPort        tck;
      TMSPort        tms;
      TRSTPort       trst;

ToResetPort

Syntax

Syntax 1

```
Module module_name {
  ToResetPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToResetPort port_name {
    Attribute att_name = att_value ;
    Source source_name ;
    ActivePolarity 0 | 1;
  }
}
```

Description

A port function that declares the name of the to-reset output port of a Module's host ScanInterface.

The to-reset port is used as the source of the ResetPort of another module. You have the option to chose the active polarity of the to-reset port.

It is important to differentiate between the active polarity, 0 or 1, and when a to-reset signal becomes active / inactive. For example, it is possible that the to-reset signal's active polarity is 0, but it is enabled if the module's input reset port turns active high (1).

If none of the parameters Source, Attribute, or ActivePolarity are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-reset port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotScanGroup, OneHotDataGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToResetPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- ActivePolarity *0|1*

  An optional keyword-value pair, that defines if the to-reset port of the module is considered active low (value = 0), or active high (value =1). A module may have at most one ActivePolarity statement. If the ActivePolarity statement is not given, the active polarity of the to-reset port is assumed to be the 1 (high).

  The activity/inactivity of the to-reset signal is given through the single ResetPort statement of the module, or, if the module does not have a ResetPort or more than one, through the global reset signal. In other words, if the reset signal is active, the to-reset signal is active as well, however, the ActivePolarity may be different.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-reset signal. A ToResetPort may have at most one Source statement. However, if the module has more than one ResetPort statement, then the Source must be specified. Further, the width of the Source must match the width of the ToResetPort.

  The to-reset signal is assumed to be active, if the source signal evaluates to 1. Note that this does not necessarily mean that the to-reset signal also evaluates to 1, since the active polarity might have been set to 0.

Note

The Source statement is currently not supported.

Example

The following shows an example ICL netlist that switches the active polarity of the reset signal between instances. Observe that the outgoing active polarity of res.trp is low, so is the incoming polarity of the module instance inst_inst.re. It is an error to connect a ToResetPort to a ResetPort with different polarities.

```
Module chip_reset {
   ScanInPort  si ;
   ScanOutPort so { Source inst_inst.so ; }

   ShiftEnPort   se ;
   CaptureEnPort ce ;
   UpdateEnPort  ue ;
   SelectPort    selC ;

   ResetPort re { ActivePolarity 1 ; }
   TCKPort tck ;

   Instance res_inst Of res {
      InputPort re   = re ;
   }

   Instance inst_inst Of inst {
      InputPort si  = si ;
      InputPort se  = se;
      InputPort ce  = ce ;
      InputPort ue  = ue ;
```

```
         InputPort sel = selC ;
         InputPort re  = res_inst.trp ;
      }
   }

   Module res {
      ResetPort re ;
      ToResetPort trp { ActivePolarity 0 ; }
   }

   Module inst {
      ScanInPort  si ;
      ScanOutPort so { Source R[0] ; }

      ShiftEnPort   se ;
      CaptureEnPort ce ;
      UpdateEnPort  ue ;
      SelectPort    sel  ;

      TCKPort tck ;

      ResetPort re { ActivePolarity 0; }

      ScanRegister R[7:0] {
         ScanInSource si ;
         ResetValue 8'b0 ;
      }
   }
```

}
```

Syntax 2

```
Module module_name {
  ToSelectPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-select port of a Module's host ScanInterface.

This port is typically used to enable the scan operation in another module. It is an active high output signal. A module may have none, one, or several to-select ports.

Parameters

- *port_name*

  A required string that identifies the name of a to-select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToSelectPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-select signal. The width of the Source must match the width of the ToUpdateEnPort.

  An optional keyword-string pair that identifies the source of the to-select signal. The width of the Source must match the width of the ToUpdateEnPort. If the to-select diagonal fans out into a ScanInterface, which is referenced by an *AllowBroadcastingOnScanInterface* property, anywhere in the hierarchy, then the Source statement is mandatory.

Note

Currently Tessent does not support any broadcasting.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the

language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following shows an example ICL netlist that switches the active polarity of the reset signal between instances. Observe that the outgoing active polarity of res.trp is low, so is the incoming polarity of the module instance inst_inst.re. Further, the SelectPort signal for the instance inst_inst is computed based on the top level DataIn signal din.

```
Module chip {
   ScanInPort  si ;
   ScanOutPort so { Source inst_inst.so ; }

   ShiftEnPort   se ;
   CaptureEnPort ce ;
   UpdateEnPort  ue ;

   DataInPort din ;
   ResetPort re { ActivePolarity 1 ; }

   TCKPort tck ;

   Instance res_inst Of res {
      InputPort gres = din ;
      InputPort re   = re ;
   }

   Instance inst_inst Of inst {
      InputPort si  = si ;
      InputPort se  = se;
      InputPort ce  = ce ;
      InputPort ue  = ue ;
      InputPort sel = res_inst.tsel ;
      InputPort re  = res_inst.trp ;
   }
}

Module res {
   ResetPort    re ;
   DataInPort   gres ;
   ToResetPort  trp  { ActivePolarity 0 ; }
   ToSelectPort tsel { Source gres; }
}

Module inst {
   ScanInPort  si ;
   ScanOutPort so { Source R[0] ; }

   ShiftEnPort   se ;
   CaptureEnPort ce ;
   UpdateEnPort  ue ;
   SelectPort    sel  ;
```

```
      TCKPort tck ;

      ResetPort re { ActivePolarity 0; }

      ScanRegister R[7:0] {
         ScanInSource si ;
         ResetValue 8'b0 ;
      }
   }
```

ToClockPort

Syntax

Syntax 1

```
Module module_name {
  ToClockPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToClockPort port_name {
    Source source_name ;
    FreqMultiplier pos_int ;
    FreqDivider pos_int ;
    DifferentialInvOf other_clock_port_name ;
    Period pos_int unit ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of a functional to-clock output port of a Module (that is, a clock that is not a test clock).

The test clock is defined through the ToTCKPort statement. A module may have zero or more to-clock ports.

A ToClockPort serves as the source of a functional clock to another module. It has three principal features:

- Modify an existing incoming functional clock with respect to its frequency by multiplication and division of the period
- Serve as an oscillator clock generation with a defined outgoing clock frequency
- Convert from differential to single-ended clock signals and vice versa.

If none of the parameters are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToClockPort of the module that is also used for the respective ports of the module in the design.

- Source *source_name*

  An optional keyword-string pair that identifies the source of the to-clock signal. A ToClockPort may have at most one Source statement. The width of the Source must match the width of the ToClockPort. The usage of Source is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- FreqMultiplier *pos_int*

  An optional keyword-positive integer number pair that identifies the multiplication factor of the to-clock outgoing clock signal with respect to an incoming clock signal of the module, referenced by Source. A ToClockPort may have at most one FreqMultiplier statement. The usage of FreqMultiplier is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- FreqDivider *pos_int*

  An optional keyword-positive integer number pair that identifies the division factor of the to-clock outgoing clock signal with respect to an incoming clock signal of the module, referenced by Source. A ToClockPort may have at most one FreqDivider statement. The usage of FreqDivider is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- DifferentialInvOf *other_clock_port_name*

  An optional keyword-string pair. Differential functional clocks are declared through the DifferentialInvOf keyword. The *other_clock_port_name* string references another ClockPort *port_name* of the same module. The usage of DifferentialInvOf is mutually exclusive from the usage of Source, FreqMultiplier, FreqDivider, and Period, leaving the DifferentialInvOf the only parameter other than the Attribute within a ToClockPort statement.

- Period *pos_int unit*

  An optional keyword-positive integer number pair, followed by an optional unit string. If used, the unit string is exactly one of these time units: s, ms, us, ns, ps. If unit is not used, the default is “ns”.

  Using the Period parameter, you can create a module that does not require an incoming clock signal to generate an outgoing clock signal of a specified period. This module is like an oscillator.

  The usage of Period is mutually exclusive from the usage of Source, FreqMultiplier, FreqDivider, and DifferentialInvOf, leaving the Period as the only parameter other than the Attribute within a ToClockPort statement.

Note

Currently Tessent does not support the Period parameter.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example represents a programmable clock generation logic that selectively uses one of two incoming reference clocks and manipulates either with a selectable set of modifiers.

```
Module chip_clock {
   ScanInPort    si ;
   ScanOutPort   so { Source clockGen_inst.so ; }
   ShiftEnPort   se ;
   CaptureEnPort ce ;
   UpdateEnPort  ue ;

   TCKPort   tck ;
   ClockPort refClkA ;
   ClockPort refClkB ;

   DataInPort  din[7:0] ;
   DataOutPort dout[7:0] { Source inst_inst.out ; }

   Instance clockGen_inst Of clockGen {
      InputPort si = si ;
      InputPort refClkA = refClkA ;
      InputPort refClkB = refClkB ;

      Parameter sclkMult = 1 ;
      Parameter sclkDiv  = 3 ;
   }

   Instance inst_inst Of instrument {
      InputPort clk = clockGen_inst.sclk ;
      InputPort in  = din ;
   }
}

Module clockGen {
   ScanInPort    si ;
   ScanOutPort   so { Source clkSelReg[0] ; }

   ClockPort refClkA ;
   ClockPort refClkB ;

   Parameter sclkMult = 1 ;
   Parameter sclkDiv  = 1 ;

   ToClockPort sclk {
     FreqMultiplier $sclkMult ;
     FreqDivider $sclkDiv ;
```

```
      Source refSelM ;
   }

   ScanRegister clkSelReg[2:0] {
      ScanInSource si ;
      ResetValue 3'b100 ;
   }

   ClockMux refSelM SelectedBy clkSelReg[2] {
      1'b1 : refClkA ;
      1'b0 : refClkB ;
   }
}

Module instrument {
   DataInPort  in[7:0];
   DataOutPort out[7:0];
   ClockPort   clk;

   Alias enable      = in[7]           { RefEnum YesNo;    }
   Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes;    }
   Alias p1[2:0]     = in[4],in[1:0];
   Alias go          = out[0]          { RefEnum PassFail; }
   Alias done        = out[1]          { RefEnum YesNo;    }
   Alias count[5:0]  = out[7:2];

   Enum PassFail {
      Pass = 1'b1;
      Fail = 1'b0;
   }
   Enum YesNo {
      Yes  = 1'b1;
      No   = 1'b0;
   }
   Enum Modes {
      red   = 4'b0011;
      blue  = 4'b1000;
      green = 4'b0100;
   }
}
```

ToTCKPort

Syntax

Syntax 1

```
Module module_name {
  ToTCKPort port_name ;
}
```

Syntax

```
Module module_name {
  ToTCKPort port_name {
    Attribute att_name = att_value ;
}
```

Description

A port function that declares the name of a test to-test clock output port of a Module (that is, a clock that is not a functional clock).

The test clock is defined through the ToClockPort statement. A module may have zero or more to-test clock ports. If a module has several to-test clock outputs, all clocks are considered equivalent in period and polarity.

Unlike the ToClockPort statement, there are no modifiers in the ToTCKPort statement. The outgoing to-test clock signal is just a pass-through of the incoming test clock.

If no parameter is used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToClockPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Example

The following example modifies the example given in ToClockPort. Here, a TCKPort and a ToTCKPort port was added to the module. Observe that ToTCKPort is just passing throught he test clock. No manipulation of the test clock signal can happen.

```
Module clockGen {
   ScanInPort    si ;
   ScanOutPort   so { Source clkSelReg[0] ; }

   TCKPort   tck ;
   ClockPort refClkA ;
   ClockPort refClkB ;

   Parameter sclkMult = 1 ;
   Parameter sclkDiv  = 1 ;

   ToTCKPort   ttck ;

   ToClockPort sclk {
     FreqMultiplier $sclkMult ;
     FreqDivider $sclkDiv ;
     Source refSelM ;
   }

   ScanRegister clkSelReg[2:0] {
      ScanInSource si ;
      ResetValue 3'b100 ;

ToTMSPort

Syntax

Syntax 1

```
Module module_name {
  ToTMSPort port_name ;
  }
}
```

Syntax 2

```
Module module_name {
  ToTMSPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-TMS port of a Module's host TAP ScanInterface. This port is typically used to provide a TMS signal to an embedded TAP controller module or to module that contains an embedded TAP controller.

If Source is used, the outgoing to-TMS signal is considered gated.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToTMSPort of the module that is also used for the respective ports of the design module.

  Any module that has a ToTMSPort must also have at least one TMSPort.

- Source *source_name*

  An optional keyword-string pair that identifies the logic signal that is considered gating the to-TMS signal of the module. A ToTMSPort may have at most one Source statement. Source is required if the module has more than one TMSPort. If the module has only one TMSPort, Source is optional and if not provided, ToTMSPort then refers to the TMSPort.

  If Source points to a data signal, the module must have exactly one TMSPort. The outgoing to-TMS signal is low (0) when the data signal evaluates to 0. If the data signal evaluates to 1, the ToTMSPort follows the TMSPort. In this sense the ToTMSPort is considered AND-gated with the TMS signal and the data signal at the input sides of the AND.

Note
The Source statement is currently not supported.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ToTRSTPort

Syntax

Syntax 1

```
Module module_name {
  ToTRSTPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToTRSTPort port_name {
    Source source_name ;
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-TRST port of a Module's host TAP ScanInterface. This port is used to distribute the TRST signal throughout the design. The to-TRST outgoing signal is always active low (0).

A module may have zero or more to-TRST ports. If a module has several to-TRST outputs, all to-TRST signals are considered equivalent.

If Source is used, the outgoing to-TRST signal is considered gated.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToTRSTPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

  An optional keyword-string pair that identifies the logic signal that is considered gating the to-TRST signal of the module. A ToTRSTPort may have at most one Source statement, and the width of the Source must match the width of the ToTRSTPort. Source is required if the module has more than one TRSTPort. If the module has only one TRSTPort, Source is optional and if not provided, ToTRSTPort then refers to the TRSTPort. Further, if the module does not have a TRSTPort, the ToTRSTPort refers to the global TRST signal.

  If Source points to a data signal, the module should have at most one TRSTPort. The outgoing to-TRST signal is inactive; that is, high (1), when the data signal evaluates to 0. If the data signal evaluates to 1, the ToTRSTPort follows the TRSTPort. In this sense the

ToTRSTPort is considered AND-gated with the (local or global) TRST signal and the data signal at the input sides of the AND.

Note

The Source statement is currently not supported.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

  ToIRSelectPort port_name ;
}
```

Syntax 2

```
Module module_name {
  ToIRSelectPort port_name {
    Attribute att_name = att_value ;
  }
}
```

Description

A port function that declares the name of the to-IR Select port of a Module.

This signal is used to select between the instruction register of a TAP controller and another scan register, usually a data register. The to-IR Select signal is always associated with the TMS signal, and if present, with the TRST signal.

If the parameter Attribute is not used, you must use Syntax 1.

Parameters

- *port_name*

  A required string that identifies the name of a to-IR Select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  It is recommended to use a port name for the ICL ToIRSelectPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Instance

Syntax

Syntax 1

```
Module module_name {
  Instance instance_name Of module_name {
    Attribute att_name = att_value ;
    InputPort moduleinputport_name = concat_signal ;
    Parameter parameter_name = parameter_value ;
    AddressValue number ;
  }
}
```

Syntax 2

```
Module module_name {
  Instance instance_name Of module_name ;
}
```

Description

The Instance statement names an instance of an ICL module. It also declares the address and/or all input connections of the instance to source signals of other instances or the top level module. Note that in ICL no output connections are listed in the Instance statement.

In addition to the input port connections, Parameters defined within the module definition may be overwritten. LocalParameter cannot be overwritten though.

Syntax 2 must be used if the module has no input ports and none of the other parameters is used.

Parameters

- *instance_name* Of *module_name*

  A required string-string pair, connected with the case-sensitive keyword ‘Of’, defining the name of the instance and referencing an existing module name of which an instance is to be created. Within a module, all instance names must be unique. Also, no module may contain an instance of itself anywhere through its hierarchy.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value are defined by you, and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- InputPort *moduleinputport_name* = *concat_signal*

  A repeatable, required keyword and string-value pair, connected with the ‘=’ symbol. For each input port defined in the module there must be exactly one such line in the Instance statement, however exceptions apply as explained below. *moduleinputport_name* must refer to an input port name of the referenced module. For modules without any input ports

the InputPort parameter may not be used. The order of the input port declaration in the referenced module and the order of the InputPort parameters can be different.

concat_signal may reference a single signal or a concatenation of signals of the same or compatible type. The type of *concat_signal* must match the type of the input port definition in the module, or must be a compatible type. *concat_signal* may only be one of these signals: reset, scan, data, read enable, write enable, clock, TCK, shift enable, capture enable, update enable, TMS, or TRST. The width of the module's port definition and *concat_signal* must match. For an indexed input port of the module, the InputPort parameter may be used as often as necessary to cover the entire index range in any order. However, overlapping indices or ranges are not allowed. For instances without the AddressValue parameter, the InputPort parameter may connect the module's WriteEnPort, ReadEnPort, AddressPort, or SelectPort to data signals; that is, a data signal is a compatible source for those port functions.

Note that not all input ports of a module must be connected explicitly. For a non-handoff module; that is, for a module that is not the top level module you hand over to a third party, several connections are automatically implied, if their source in the parent module can be determined unambiguously. It is legal to list these connections through the InputPort parameter, but it is not necessary. The following connections are automatically implied for non-hand-off module instances that do not have the AddressValue statement: TCK, shift enable, capture enable, update enable.

- Parameter *parameter_name* = *parameter_value*

  A repeatable, optional keyword and string-value pair, connected with the "=" symbol. The referenced *parameter_name* must have been defined in the module referenced by *module_name*; also the type of *parameter_value* must match the type used in the module for the parameter.

  Using the Parameter statement again within Instance overwrites the respective parameter value set in the module definition, but only for the current instance. Another instance of the module may use another overwrite value, or may use the original value defined in the module. Through this construct, ICL can define parameterized modules, where the final parameter is defined during each instantiation of the module.

- AddressValue *number*

  A required keyword and number pair, if this instance is part of the OneHotDataGroup. The AddressValue parameter may not be used if the instance if not part of a OneHotDataGroup. Within the OneHotDataGroup, the *number* declares a part of the address that is associated with the instance. The final address of a DataRegister is determined by the sum of all addresses along the hierarchical instance path leading to the data register. In this sense *number* is only one element of the sum, comprising the address of a data register of the OneHotDataGroup.

  The following connections are automatically implied for non-hand-off module instances that do have the AddressValue statement: TCK, the instance's AddressPort is assumed to be connected to the logical address signal of the parent module, the instance's WriteEnPort is assumed to be connected to the WriteEnPort of the parent module, the instance's

ReadEnPort is assumed to be connected to the ReadEnPort of the parent module, and the instance's DataInPort is assumed to be connected to the logical data in signals of the parent module.

Note

In IEEE P1687 the Instance statement describes the "AllowBroadcastOnScanInterface" parameter. This parameter is currently not supported in Tessent.

Example 1

The following example demonstrates the usage of automatic default connections in the common case of a scan interface. Observe that the instance declaration for tdr_inst of module tdr only declares the scan input port connection. TCK and all the enable signals are connected fully automatically to the respective signals of the parent module. Explicit connections are only necessary, if there are multiple signals of the same type in the parent module, for example two select ports.

```
Module chip_tdr {
   ScanInPort       si;
   ScanOutPort      so       { Source tdr_inst.so; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   Instance tdr_inst Of tdr {
     InputPort si = si ;
   }
}

Module tdr {
   ScanInPort       si;
   ScanOutPort      so       { Source R[0]; }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   ScanRegister R[7:0] {
      ScanInSource     si;
      ResetValue       8'b0 ;
   }
}
```

Example 2

The following example demonstrates not only the usage of the OneHotDataGroup, but also the usage of the InputPort parameter and some of the compatible signal connections. Observe that module "top" does have neither a ReadEnPort, nor a WriteEnPort. Instead it has 2 DataInPort statements that are connected to the respective input ports of the instances of module "phy". Since the connection of the data signals of the parent module (that is, top) to the instances is

done implicitly, by the order of declaration, it is important that the 16 data input bits of DataIn are declared before the 2 bits of the write and read enable. Also note that the module top defines just one AddressPort of 8 bits, which is implicitly mapped to the two 4-bit AddressPorts of phy in their order of declaration. Further, observe that the AddressPort of “bank” only 2-bits wide, since only two bits are required for this module’s operation.

```
Module top {
   AddressPort   address[7:0] ;
   DataInPort    dataIn[15:0] ;

   DataInPort    write_enable ;
   DataInPort    read_enable ;

   DataOutPort   dataOut[15:0] {
     Source outMux[15:0] ;
     Enable read_enable ;
   }

   OneHotDataGroup outMux[15:0] {
     Instance phy1 Of phy {
       AddressValue 2'b01, 6'b000000 ;
       InputPort we = write_enable ;
       InputPort re = read_enable ;
     }

     Instance phy2 Of phy {
       AddressValue 2'b10, 6'b000000 ;
       InputPort we = write_enable ;
       InputPort re = read_enable ;
     }
   }
}

Module phy {
   WriteEnPort 7 we ;
   ReadEnPort    re ;
   AddressPort   address1[3:0] ;
   AddressPort   address2[3:0] ;

   DataInPort    dataIn1[7:0] ;
   DataInPort    dataIn2[7:0] ;
   DataOutPort   dataOut[15:0] { Source outMux[15:0] ; }

   OneHotDataGroup outMux[15:0] {
     Instance bank1 Of bank {
       AddressValue 4'b0001,2'b00 ;
     }
     Instance bank2 Of bank {
       AddressValue 4'b0010,2'b00 ;
     }
   }
}

Module bank {
   WriteEnPort   we ;
   ReadEnPort    re ;
   AddressPort   address[1:0];
```

```
      DataInPort    dataIn[15:0];
      DataOutPort   dataOut[15:0] { Source outMux[15:0] ; }

      OneHotDataGroup outMux[15:0] {
//      AddressValue 2'bx,4'bx,2'b<num>
        DataRegister D0[15:0] { AddressValue 2'b00 ; }
        DataRegister D1[15:0] { AddressValue 2'b01 ; }
        DataRegister D2[15:0] { AddressValue 2'b10 ; }
        DataRegister D3[15:0] { AddressValue 2'b11 ; }
      }
    }
```

Parameter

Syntax

Syntax 1 : Defining a parameter

```
Module module_name {
  Parameter parameter_name = parameter_value ;
}
```

Syntax 2 : Optionally overwriting a parameter in an Instance statement

```
Module module_name {
  Instance instance_name of other_module_name {
    Parameter parameter_name = parameter_value ;
  }
}
```

Description

With the help of the Parameter statement you can define a named variable and assign a default value to it.

The default value is specified in the module that declares the Parameter. The value can be overwritten with every instance of the Module. Through this, ICL allows you to create parameterized modules.

You build a reference to the Parameter by using the '$' symbol in front of the parameter_name.

The parameter reference can be used in many locations, for example in an Enum statement. The reference will be resolved to the current value before the statement the Parameter is evaluated.

Parameters

- *parameter_name = parameter_value*

  A required string-value pair, connected with the '=' symbol. The parameter name must be unique across all Parameter and LocalParameter statements within the module. The parameter value may be exactly one of the following: an unsized number, a sized number, or a string. A parameter reference representing an unsized number may only be used where an unsized number is expected. Similarly for the sized number. A parameter reference representing a string may only be used in an attribute within any statement in the module, or within a Callback function. Places where a parameter reference is allowed include an attribute value, the index value for a vector identifier, or where a size or unsized number is allowed. For example, you cannot use a parameter to substitute any arbitrary number, such as creating object names, like an Instance name "inst$size", where "size" is a parameter

  Although parameters can be used to define other parameters, a circular definition is not allowed.

Note

Currently Tessent does not support the Callback functionality.

Example 1

The following example shows several usages of Parameter. In particular observe that the Parameter ‘Width’ is used to parameterize the values in the enumeration table.

```
Module inst {
   ScanInPort       si;
   ScanOutPort      so      {  Source R[0];   }
   TCKPort          tck;

   Parameter  Width  = 8 ;
   Parameter  Regmax = $Width - 1 ;
   Parameter  userValue = 8'hff ;
   Parameter  Val_A  = 4'b1001, $userValue, 4'b1111 ;
   Parameter  RegName = "R" ;

   LocalParameter  Regmin = 0 ;

   ScanRegister R[$Regmax:$Regmin] {
      Attribute     Register = "$RegName($RegMax:$RegMin)" ;
      ScanInSource  si;
      ResetValue    Reset ;
      RefEnum       SomeValues ;
   }

   Enum SomeValues {
       Reset = $Width'b0 ;
       User1 = $userValue ;
   }
}
```

Example 2

The following example uses the module defined above. In its instantiation, the parameters ‘Width’ and ‘userValue’ will be overwritten. This allows ICL to create parameterized modules, where the size of registers will be fixed during the instantiation of the module and not during the declaration of the module.

```
Module top {
   ScanInPort       si;
   ScanOutPort      so      {  Source inst2.so;   }
   ShiftEnPort      se;
   SelectPort       en;
   CaptureEnPort    ce;
   UpdateEnPort     ue;
   TCKPort          tck;

   Instance inst1 Of inst {
      InputPort si = si ;
      Parameter Width = 16 ;
      Parameter userValue = 16'hffff ;
   }

   Instance inst2 Of inst {
      InputPort si = inst1.so ;
      Parameter Width = 4 ;
      Parameter userValue = 4'ha ;
```

```
        }
    }
```

Related Topics

LocalParameter
Instance
Alias
Enum

LocalParameter

Syntax

```
Module module_name {
  LocalParameter parameter_name = parameter_value ;
}
```

Description

A LocalParameter has the same semantic and use model as the Parameter statement. The only difference is that a LocalParameter cannot be overwritten in the Instance statement.

Parameters

- *parameter_name = parameter_value*

  A required string-value pair, connected with the '=' symbol. The parameter name must be unique across all Parameter and LocalParameter statements within the module. The parameter value may be exactly one of the following: an unsized number, a sized number, or a string. A parameter reference representing an unsized number may only be used where an unsized number is expected. Similarly for the sized number. A parameter reference representing a string may only be used in an attribute within any statement in the module, or within a Callback function. Places where a parameter reference is allowed include an attribute value, the index value for a vector identifier, or where a size or unsized number is allowed. For example, you cannot use a parameter to substitute any arbitrary number, such as creating object names, like an Instance name "inst$size", where "size" is a parameter

  Although parameters can be used to define other parameters, a circular definition is not allowed.

Related Topics

Parameter
Instance
Alias
Enum

Enum

Syntax

```
Module module_name {
  Enum enum_name {
    name = value ;
  }
}
```

Description

With the Enum statement, ICL introduces an enumeration table that links a mnemonic string to an arbitrary value. This string can then be used in lieu of the value at places like DataInPort, DataOutPort, and LogicSignal. For the ScanRegister and the DataRegister the string can be used for the DefaultLoadValue, ResetValue, and CaptureSource (ScanRegister only).

Further, PDL commands like iWrite or iRead can also use the name instead of the value. Choosing meaningful mnemonics can make both, ICL and PDL, much more human readable.

In no usage of the enumeration table are you limited to only the names listed in the table. You are free to continue using any legal value, and in particular values not listed in the table. The example below shows such a case.

Parameters

- *enum_name*

  A required string that identifies the name of the enumeration table. Using this name the RefEnum parameter inside the ScanRegister statement, for example, can reference the enumeration table. The *enum_name* must be unique among all Enum statements within the module.

- *name = value*

  A required, repeatable string-value pair, connected with the '=' symbol. These pairs make up the enumeration table. All values must be of the same width, and the names must be unique within the same Enum. An enumeration table must contain at least one name-value pair.

Example

The following enumeration table shows several examples of value definitions. The width of the value depends on the usage of the table entries in other objects, like ScanRegister or DataInPort, referenced by RefEnum. within these statements. The number type is not relevant as shown. Also observe that two Parameter were defined, which are used in the enumeration table 'Modes'. As usual, these parameters could be overwritten differently in each instance of the module.

```
Module instrument {
   DataInPort  in[7:0];
   DataOutPort out[7:0];
   ClockPort   clk;
```

```
   Alias enable      = in[7]           { RefEnum YesNo;    }
   Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes;    }
   Alias p1[2:0]     = in[4],in[1:0];
   Alias go          = out[0]          { RefEnum PassFail; }
   Alias done        = out[1]          { RefEnum YesNo;    }
   Alias count[5:0]  = out[7:2];

   Parameter userEnum1val = 4'b1111 ;
   Parameter userEnum2val = 4'h22 ;

   Enum PassFail {
      Pass = 1'b1;
      Fail = 1'b0;
   }

   Enum YesNo {
      Yes  = 1'b1;
      No   = 1'b0;
   }

   Enum Modes {
      none      = 4'b0 ;
      red       = 4'b0011 ;
      blue      = 4'haa ;
      green     = 4'd9 ;
      userEnum1 = $userEnum1val ;
      userEnum2 = $userEnum2val ;
   }
}
```

Next, here is a snippet of a dofile, writing to the ‘mode’ Alias of the module, using the names defined in the ‘Mode’ enumeration table which is associated with the alias through the RefEnum parameter. The done Alias is then read from ‘out’.

```
open_pattern_set enumTest
  iWrite mode red
  iApply
  iWrite mode 0b1010
  iApply
  iRead  done Yes
  iApply
close_pattern_set
write_patterns enumTest.pdl -pdl
```

The following lists the contents of the saved PDL file enumTest.pdl:

```
iProcsForModule instrument

iProc enumTest {} {

   iWrite in[6] 0b0
   iWrite in[5] 0b0
   iWrite in[3] 0b1
   iWrite in[2] 0b1
   iApply

   iWrite in[6] 0b1
   iWrite in[5] 0b0
```

```
        iWrite in[3] 0b1
        iWrite in[2] 0b0
        iApply

        iRead out[1] 0b1
        iApply
    }
```

Alias

Syntax

Syntax 1

```
Module module_name {
  Alias alias_name = concat_signal ;
}
```

Syntax 2

```
Module module_name {
  Alias alias_name = concat_signal {
    RefEnum enum_name ;
    AccessTogether ;
    iApplyEndState value ;
  }
}
```

Description

The Alias statement collects signals from different origins to form a named, new, virtual signal.

The name of the alias can be used in any operation or construct where the original signals would have been allowed. For example, PDL commands like iWrite or iRead can use the alias name. Choosing meaningful alias names can make both ICL and PDL, much more human readable.

A second usage of the Alias statement is to instruct Tessent to automatically return to a specified value for the selected signals. Typically this feature is used to return a write-enable signal to the inactive value assignment automatically, once the write operation has been completed.

If none of the parameters RefEnum, AccessTogether, or iApplyEndState are used, you must use Syntax 1.

The name of the Alias must be unique among all port names, and among all the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal.

Parameters

- *alias_name = concat_signal*

  A required string-string pair, connected with the '=' symbol. The *alias_name* defines the name of the alias, whereas *concat_signal* refers to one signal, or a concatenation of signals. Such a concatenation of signals is created by a signal name followed by a comma (','), followed by another signal name etc. The concatenated signals can only be from DataInPort, ScanInPort, DataOutPort, or ScanOutPort. The width of the alias name should match the width of the concatenated signal.

  An alias name can become part of another Alias statement, however circular definitions are not allowed. Further, if any of the signals in the concatenation has more than one level of hierarchy; that is, the hierarchical instance-port path name contains the dot ("."), the Alias may not be used in any other ICL statements, but only in PDL.

- RefEnum *enum_name*

  An optional keyword-string pair that references the name of an Related Topics table. Using the enumeration table, the writing to the aliased signal can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. You are still allowed to read or write any value, including those not listed in the enumeration table. An Alias statement may have at most one RefEnum parameter.

- AccessTogether

  An optional keyword that requests Tessent to operate all signals listed in *concat_signal* at the same time. If this turns out to be not possible, for example, based on mutually exclusive hardware requirements, an error will be returned. Without this keyword, Tessent is allowed to find a solution where some of the signals are operated first, followed by operating another set of signals in the *concat_signal* Alias.

Note

Currently Tessent does not support the AccessTogether parameter.

- iApplyEndState *value*

  An optional keyword-string pair that identifies the value to which the signals listed *concat_signal* will return to automatically, if ever changed by an iWrite command. The value will return with the next iApply PDL command. Typically this feature is used to return the write-enable signal to the inactive value assignment automatically, once the write operation has been completed.

  There are additional conditions to the signals and value used in the Alias and iApplyEndState statement and parameter: All resolved signals must be legal targets of the iWrite command; *value* may not contain unknown values; if a signal is part of multiple iApplyEndState parameters, all specified values must be the same; if the signals resolve to register bits, either ScanRegister or DataRegister, the register must have a ResetValue parameter defined and the reset value should match the iApplyEndState-value for these signals; if a signal does not resolve to register bits, it must resolve to primary inputs, no other resolved signal source is allowed for the *concat_signal*, if the iApplyEndState parameter is used; further, there may not be a DataOutPort with an Enable parameter between the resolved signal source and the signal specified in *concat_signal* of the Alias statement.

Example

The following example shows several usages of the Alias statement.

```
Module instrument {
   DataInPort  in[8:0];
   DataOutPort out[7:0];
   ClockPort   clk;

   Alias write_en    = in[8]{ RefEnum YesNo; iApplyEndState 1'b0; }
   Alias enable      = in[7]           { RefEnum YesNo;    }
   Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes;    }
   Alias p1[2:0]     = in[4],in[1:0];
```

```
      Alias go          = out[0]          { RefEnum PassFail; }
      Alias done        = out[1]          { RefEnum YesNo;    }
      Alias count[5:0]  = out[7:2];

      Enum PassFail {
         Pass = 1'b1;
         Fail = 1'b0;
      }

      Enum YesNo {
         Yes  = 1'b1;
         No   = 1'b0;
      }

      Enum Modes {
         none      = 4'b0 ;
         red       = 4'b0011 ;
         blue      = 4'haa ;
         green     = 4'd9 ;
      }
   }
```

LogicSignal

Syntax

```
Module module_name {
  LogicSignal signal_name {
    expression ;
  }
}
```

Description

The LogicSignal statement creates a new signal named *signal_name*, which itself can then be referenced in other ICL statements, and in particular other LogicSignal statements.

Using the LogicSignal statement, logical operations between signals like AND or EXOR can be implemented.

Parameters

- *signal_name*

  A required string that identifies the newly created signal name. The value it assumes depends on the result of the evaluation of *expression*.

  The name of the LogicSignal must be unique among all port names, and among all the following objects: ScanRegister, DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, Alias.

  In any case, the width of signal_name is always 1. In particular, comparisons and Boolean logic operations return 1’b1, if the expression evaluates to true, and 1’b0, if the expression evaluates to false.

- *expression*

  A required string that defines a Boolean expression that evaluates to a single-bit result, based on the signals and their value used in the expression.

  The common Boolean and Logical operators are supported. In decreasing order of preference, these are: Boolean not (!), Bitwise not (~), logical AND (&&) and logical OR(||), bitwise AND (&), bitwise OR (|), and bitwise XOR (^), logical equality (==) and ineqeuality (!=).

  All operators are left-to-right associative, and operators with equal precedence are evaluated left-to-right. Associativity and precedence may be expressly specified with parentheses ().

  Valid operands are registers, ports, sized and unsized numbers, logical signals, as well as parameters and aliases that resolve into those. In addition, signals can be concatenated.

  For expressions containing unsized numbers, it must be possible to determine the required width of the unsized number unambiguously. If the width must be extended, the additional bits will either be filled with 0, if the most significant bit is either 0 or 1, or the bits will be filled with unknown (x).

For the logical equality and inequality operation, the width of the operands on either side of the operator must be the same.

Any parameter reference will be resolved before the expression is evaluated.

Enumeration table entries can be used for operands which are used in their entirety in the expression, and not just a part of the operand. The operand must have declared its binding to this enumeration by means of the RefEnum statement. Enumeration values are allowed only in combination with equality (==) and inequality (!=) operators. See the example below.

Example

The following example shows several usages of the LogicalSignal statement. sig1 demonstrates the usage of an enumeration table value entry. Note that ‘mode[3:0]’ is the entire operand for which the Enum ‘Modes’ applies. Therefore, any table entry may be used for this operand. sig2 shows the usage of concatenation, the expansion of an unsigned number and the usage of a parameter reference. Observe that the width of the right operand is 5, whereas the width of the sized elements of the left operand is 3. Therefore, the unsigned number ‘0’ will be expanded to width 2, matching the width of the right operand. Lastly, sig3 shows an example of bit-operations.

```
Module instrument {
   [ ... ]
   DataInPort  in[7:0];
   [ ... ]
   Alias enable      = in[7]           { RefEnum YesNo;    }
   Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes; }

   Parameter user1 = 4'b1010 ;

   LogicSignal sig1 { (mode==red) && (enable==1'b1) ; }
   LogicSignal sig2 {  in[4],1'b1,in[0],0 == 1'b0,$user1 ; }
   LogicSignal sig3 { (in[6:5] | in[3:2]) != 2'b10 ; }

   Enum Modes {
      none      = 4'b0 ;
      red       = 4'b0011 ;
      blue      = 4'haa ;
      green     = 4'd9 ;
   }
   [ ... ]
}
```

ScanRegister

Syntax

```
Module module_name {
  ScanRegister register_name {
    Attribute att_name = att_value;
    ScanInSource scan_in_source;
    CaptureSource capture_source;
    DefaultLoadValue default_load_value;
    ResetValue reset_value;
    RefEnum enum_name;
  }
}
```

Description

The statement ScanRegister defines and names a scan register of a certain width and with certain properties. These properties, like the reset value, are described through parameters of the scan register.

Parameters

- *port_name*

  A required string that identifies the name of a the scan register of the module. The name of the ScanRegister must be unique among all port names, and among all the following objects: DataRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

- Attribute *att_name* = *att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you and may be ignored by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- ScanInSource *scan_in_source*

  A required keyword-string pair that identifies the signal that is providing the scan data to the left most bit of the scan chain. If *scan_in_source* references another scan register, it must reference the right-most bit of that scan register (that is, the ‘scan out bit’).

  For ranged scan registers; that is, scan registers that have a width > 1, the scan register always shifts from left to right, independently if the left most index is larger than the right most index, or vice-versa.

- CaptureSource *capture_source*

  An optional keyword-string pair that identifies the signal from which the ScanRegister captures data in response to the CaptureEnPort and TCKPort signal. If used, the width of *capture_source* must match the width of the register.

- DefaultLoadValue *default_load_value*

  An optional keyword-string pair that identifies the value that each scan register cell will assume if no user-defined value had been written to it beforehand and if no reset had been triggered. If used, the width of *default_load_value* must match the width of the register.

  When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same Scan Register statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- ResetValue *reset_value*

  An optional keyword-string pair that identifies the value that each scan register cell will assume as a response to an active reset signal of the module. In more detail, it is the update stage of the scan register that assumes the declared reset value. If used, the width of *reset_value* must match the width of the register. If the ResetValue parameter is not used, the scan register does not respond to the module's incoming reset signal. However, if the module contains scan registers with a ResetValue parameter, the module must have only one ResetPort statement.

  When both the DefaultLoadValue parameter the ResetValue parameter exist in the same Scan Register statement, the non-x bit values of *reset_value* mast match those of *default_load_value*.

- RefEnum *enum_name*

  An optional keyword-string pair that references the name of an Related Topics table. Using the enumeration table, reading and writing to the scan register can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. It is still allowed to read or write any value, including those not listed in the enumeration table. A ScanRegister statement may have at most one RefEnum parameter. In addition, the width of the elements in the enumeration table must match the width of the scan register.

Additional Rules

A ScanRegister is considered to be in the active scan path if it responds to the ShiftEnPort signal associated to the ScanInterface through an active ScanInterface. It holds its data as long as the ShiftEnPort remains inactive (low) between the capture- and the update-cycle.

Any scan register bit that controls parts of a scan network (that is, the select line of a ScanMux, a SelectPort or ToSelectPort), or is part of a ScanInterface, anywhere in the hierarchy of the design, will have a non-x reset value (that is, a reset value of 0 or 1).

If a scan register bit is the source of a data signal, the scan register must have an update stage that (or an equivalent implementation) which changes only in response to an active UpdateEnPort signal.

It is important to understand the rules which determine what value gets loaded into the scan register bits. Assume no user-defined care bits have ever been written to any scan register bits. Now an iApply block accesses the ScanRegister. The scan register bits will assume a value in this order of preference: The specified values required to satisfy the operations in the iApply

block; the value DefaultLoadValue specifies, if is a 0 or 1; the value ResetValue specifies, if it is a 0 or 1; any scan register bits still unassigned a 0 or 1, will be loaded with a 0.

If a scan register receives a reset signal, all scan register bits assume the value specified in *reset_value*. For the remaining x-values apply the sequence of events outlined in the paragraph above.

If a ScanRegister is on the active scan path (that is, a shift operation may happen), any scan register bits that are not required to satisfy the operations in the current iApply block will remain unchanged from their current value.

Example 1

The following shows a complete example ICL module definition of a TAP controller. Observe that the two different ScanRegisters: 'IR' has a width of 3, whereas 'bypass' has a width of 1. 'IR' must have as ResetValue parameter defined, since it controls the ScanMux DRMux. Further, observe the usage of the name of the scan register in the expression of the LogicSignal 'sel1'.

```
Module tap {
   TCKPort         tck;
   ScanInPort      tdi;
   ScanOutPort     tdo       {  Source IRMux; }
   TMSPort         tms;
   TRSTPort        trst;
   ToSelectPort    tdrEn1    {  Source sel1;  }
   ScanInPort      fromTdr1;
   ToSelectPort    tapEn1    {  Source IR[2]; }
   ToCaptureEnPort tce;
   ToShiftEnPort   tse;
   ToUpdateEnPort  tue;

   ScanInterface clientTAP {
     Port tdi; Port tdo;
     Port tms; Port trst;
   }

   ScanInterface hostTAP   {
     Port fromTdr1; Port tdrEn1;
     Port tce; Port tse; Port tue;
   }

   Instance fsm_i Of fsm  {
      InputPort tck  = tck;
      InputPort tms  = tms;
      InputPort trst = trst;
    }

   ScanRegister IR[2:0] {
      CaptureSource  3'b001;
      ResetValue     3'b000;
      ScanInSource   tdi;
   }

   ScanRegister bypass {
      CaptureSource  1'b0;
```

```
      ScanInSource   tdi;
   }

   ScanMux IRMux SelectedBy fsm_i.irSel {
      1'b0 : DRMux;
      1'b1 : IR[0];
   }

   ScanMux DRMux SelectedBy IR[2:0] {
      3'bx00 : bypass;
      3'bx01 : fromTdr1;
   }

   LogicSignal sel1 {  IR[2:0] == 3'bx01; }
}

Module fsm {
   TCKPort        tck;
   TMSPort        tms;
   TRSTPort       trst;
   ToIRSelectPort irSel;
   ToResetPort    tlr;
}
```

Example 2

The following example shows an ICL module definition of a sensor where CaptureSource can be used to combine multiple DataInPorts to form the width of the ScanRegister.

```
Module sensor {
   TCKPort        tck;
   TRSTPort       rst;
   ScanInPort     si;
   ScanOutPort    so;      {  Source  S_reg[0]; }
   CaptureEnPort  capture_en;
   ShiftEnPort    shift_en;
   UpdateEnPort   update_en;
   SelectPort     sel_en;
   DataInPort     sdata_in [2:0];
   DataInPort     sens_from;
   DataInPort     cntrl [1:0];

ScanRegister S_reg [5:0] {
   ResetValue     6’b000000;
   CaptureSource  sdata_in, sens_from, cntrl ;
   ScanInSource   si;
  }
}
```

DataRegister

Syntax

Syntax 1

```
Module module_name {
  DataRegister register_name {
    WriteDataSource concat_signal ;
    WriteEnSource enable_source ;

    ResetValue reset_value ;
    DefaultLoadValue load_value ;
    RefEnum enum_name ;
    Attribute att_name = att_value;
  }
}
```

Syntax 2

```
Module module_name {
  DataRegister register_name {
    AddressValue address_value ;

    ResetValue reset_value ;
    DefaultLoadValue load_value ;
    RefEnum enum_name ;
    Attribute att_name = att_value;
  }
}
```

Description

The statement DataRegister defines and names a data register of a certain width and with certain properties. These properties, like the reset value, are described through parameters of the data register. The DataRegister is used for parallel reading and writing as opposed to a ScanRegister, which offers a scan-based access.

There are three, mutually exclusive types of DataRegisters: A Selectable DataRegister, for which a signal must be defined from which the DataRegister captures data; an Addressable DataRegister, for which an AddressValue must be specified; and a CallBack DataRegister. You should use Syntax 1 if you have a Selectable DataRegister. You should use Syntax 2 if you have an Addressable DataRegister.

Further, the Addressable DataRegister can only be used inside a OneHotDataGroup, and inside a OneHotDataGroup there can only be Addressable DataRegisters.

Note

Currently Tessent does not support the Callback functionality.
Also the DefaultLoadValue parameter is not supported at the moment.

Parameters

- *register_name*

  A required string that identifies the name of a data register of the module. The name of the DataRegister must be unique among all port names, and among all the following objects: ScanRegister, ScanMux, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

- ResetValue *reset_value*

  An optional keyword-string pair that identifies the value that each data register cell will assume as a response to an active reset signal of the module. In more detail, it is the update stage of the scan register that assumes the declared reset value. If used, the width of *reset_value* must match the width of the register. If the ResetValue parameter is not used, the data register does not respond to the module's incoming reset signal. However, if the module contains data registers with a ResetValue parameter, the module must have only one ResetPort statement.

  When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same DataRegister statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

Note

Currently Tessent supports only the reset of a DataRegister with a ResetValue parameter following the global reset signal.

- DefaultLoadValue *default_load_value*

  An optional keyword-string pair that identifies the value that each data register cell will assume if no user-defined value had been written to it beforehand and if no reset had been triggered. If used, the width of *default_load_value* must match the width of the register.

  When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same DataRegister statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- RefEnum *enum_name*

  An optional keyword-string pair that references the name of an Enum table. Using the enumeration table, reading and writing to the data register can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. It is still allowed to read or write any value, including those not listed in the enumeration table. A DataRegister statement may have at most one RefEnum parameter. In addition, the width of the elements in the enumeration table must match the width of the data register.

- Attribute *att_name = att_value*

  A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you and may be ignored

by any IJTAG software tool. Tessent understands several port attributes and pin attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- WriteDataSource *concat_signal*

  A keyword and string pair required for a selectable DataRegister. *concat_signal* references a single signal or a concatenation of signals from where the DataRegister will capture data in response to a write request when WriteEnSource turns active (high). concat_signal must refer either to the module's DataInPorts, another DataRegister, or to a ScanRegister.

- WriteEnSource *enable_source*

  A keyword and string pair required for a selectable DataRegister. *enable_source* references a 1-bit wide signal which determines when the DataRegister can capture data from WriteDataSource. The DataRegister will capture data in response to a write request when WriteEnSource turns active (high).

- AddressValue *address_value*

  A keyword and number pair required if an Addressable DataRegister; that is, the DataRegister is part of the OneHotDataGroup. The AddressValue parameter may not be used if the DataRegister if not part of a OneHotDataGroup. Within the OneHotDataGroup, the *number* declares a part of the address that is associated with the DataRegister. The final address of a DataRegister is determined by the sum of all addresses along the hierarchical instance path leading to the data register. In this sense *number* is only one element of the sum, comprising the address of a data register of the OneHotDataGroup.

  The DataRegister will be loaded from the logical data-in signal with the right most indices first, when the DataRegister's address has been applied and the module's WriteEnPort is active (high). The address of a DataRegister is computed by adding all address_values of all Instances leading to the DataRegister.

  Similarly, reading from the Addressable DataRegister requires the module's ReadEnPort being active (high), and the address of the DataRegister being applied.

Example

The following example shows a selectable data register. An example of addressable data registers can be found with the OneHotDataGroup statement, as well as with the Instance statement.

Observe the usage of the Parameter statement as well as Parameter overwrites. Further observe how the write enable signal is computed for the data registers in module bank using a LogicSignal statement and concatenation of the parameterized signals of the comparisons.

All together, this example shows how a selectable DataRegister can be used very much in a way of an addressable DataRegister, but without any of the constraints that come with an addressable DataRegister. In this particular implementation, the read and write enable signal of bank are explicitly managed (see for example, the usage of Dx_Mux). Depending on your DataRegister implementation, you may be able to relax this and allow reading from and writing

to a data register simultaneously. Tessent sets up constraints for the IJTAG software such that no race conditions can occur.

```
Module chip_selectable_dataregister {
   DataInPort  write_enable ;
   DataInPort  read_enable ;

   DataInPort  address[7:0] ;
   DataInPort  dataIn[15:0] ;
   DataOutPort dataOut[15:0] { Source outMux[15:0] ; }

   Parameter bank1Address = 4'b0011 ;
   Parameter bank2Address = 4'b1100 ;

   DataMux outMux[15:0] SelectedBy address[7:4] {
     $bank1Address : bank1.dataOut[15:0] ;
     $bank2Address : bank2.dataOut[15:0] ;
   }

   Instance bank1 Of bank {
     InputPort we = write_enable ;
     InputPort re = read_enable ;
     InputPort dataIn[15:0] = dataIn[15:0] ;
     InputPort address[3:0] = address[3:0] ;
   }

   Instance bank2 Of bank {
     InputPort we = write_enable ;
     InputPort re = read_enable ;
     InputPort dataIn[15:0] = dataIn[15:0] ;
     InputPort address[3:0] = address[3:0] ;
     Parameter D0_Address = 4'b1000 ;
     Parameter D1_Address = 4'b1100 ;
   }
}

Module bank {
   DataInPort    we ;  Alias weR = we { iApplyEndState 1'b0 ; }
   DataInPort    re ;

   DataInPort    address[3:0];
   DataInPort    dataIn[15:0];
   DataOutPort   dataOut[15:0] { Source Dx_Mux[15:0] ; Enable re; }

   Parameter D0_Address = 4'b0000 ;
   Parameter D1_Address = 4'b0001 ;

   DataMux Dx_Mux[15:0] SelectedBy we,address[3:0] {
     1'b0, $D0_Address : D0[15:0] ;
     1'b0, $D1_Address : D1[15:0] ;
   }

   LogicSignal D0_wen {  re,we,address[3:0] == 2'b01, $D0_Address ; }
   DataRegister D0[15:0] {
     ResetValue       16'b0 ;
     WriteEnSource    D0_wen ;
     WriteDataSource  dataIn[15:0] ;
```

```
        }

        LogicSignal D1_wen {  re,we,address[3:0] == 2'b01, $D1_Address ; }
        DataRegister D1[15:0] {
          ResetValue       16'b0 ;
          WriteEnSource    D1_wen ;
          WriteDataSource  dataIn[15:0] ;
        }
    }
```

DataInPort
DataOutPort
ScanRegister
OneHotDataGroup

ScanMux

Syntax

```
Module module_name {
  ScanMux mux_name SelectedBy mux_select_signal {
    mux_select_value : scan_source_name ;
  }
}
```

Description

The ScanMux statement creates and names a scan multiplexor.

IEEE P1687 differentiates between a scan multiplexor, a data multiplexor, and a clock multiplexor. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexor only switches between scan signals, the data multiplexor only switches between data signals, and the clock multiplexor only switches between clock signals. No signal types may be mixed for any of the multiplexors. The select signal of the multiplexors may be sourced only by data signals. Note that the parallel output of a scan register is also a data signal.

A common design structure is to have a ScanMux, with a 1-bit TDR at the output of the ScanMux, and the parallel output of the TDR connected to the select input of the mux. In this configuration, the TDR behind the mux is always on the scan path, independent of which scan input ports of the mux have been selected. Through this TDR, Tessent can select either of the scan input ports of the mux as needed.

Parameters

- *mux_name*

  A string that identifies the name of a scan multiplexor of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: ScanRegister, DataRegister, DataMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  Using this name, the outgoing signal of the multiplexor can be referenced. The width of *mux_name* must match the with of the *scan_source_name*.

- *mux_select_value* : *scan_source_name*

  A repeatable string-string pair, connected by a colon symbol ‘:’. A ScanMux must have at least one *mux_select_value* - *scan_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

  The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *scan_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Example

The following shows usages of all the multiplexor types.

```
Module chip2 {
   ScanInPort  siA ;
   ScanInPort  siB ;
   ScanOutPort so      { Source scanM ; }

   ShiftEnPort   se1 ;
   CaptureEnPort ce1 ;
   UpdateEnPort  ue1 ;

   ShiftEnPort   se2 ;
   CaptureEnPort ce2 ;
   UpdateEnPort  ue2 ;

   TCKPort tck ;
   ClockPort clkA ;
   ClockPort clkB ;
   ToClockPort clk { Source clockM ; }

   DataInPort   dselA ;
   DataInPort   dselB[2:0] ;

DataMux

ClockMux

DataMux

Syntax

```
Module module_name {
  DataMux mux_name SelectedBy mux_select_signal {
    mux_select_value : data_source_name ;
  }
}
```

Description

The DataMux statement creates and names a data multiplexor.

IEEE P1687 differentiates between a scan multiplexor, a data multiplexor, and a clock multiplexor. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexor only switches between scan signals, the data multiplexor only switches between data signals, and the clock multiplexor only switches between clock signals. No signal types may be mixed for any of the multiplexors. The select signal of the multiplexors may be sourced only by data signals.

Parameters

- *mux_name*

  A string that identifies the name of a data multiplexor of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: ScanRegister, DataRegister, ScanMux, ClockMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  Using this name, the outgoing signal of the multiplexor can be referenced. The width of *mux_name* must match the with of the *data_source_name*.

- *mux_select_value* : *data_source_name*

  A repeatable string-string pair, connected by a colon symbol ':'. A DataMux must have at least one *mux_select_value* - *data_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

  The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *data_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Example

The following shows usages of all the multiplexor types.

```
Module chip2 {
   ScanInPort  siA ;
   ScanInPort  siB ;
   ScanOutPort so      { Source scanM ; }

   ShiftEnPort   se1 ;
```

```
      CaptureEnPort ce1 ;
      UpdateEnPort  ue1 ;

      ShiftEnPort   se2 ;
      CaptureEnPort ce2 ;
      UpdateEnPort  ue2 ;

      TCKPort tck ;
      ClockPort clkA ;
      ClockPort clkB ;
      ToClockPort clk { Source clockM ; }

      DataInPort   dselA ;
      DataInPort   dselB[2:0] ;
      DataOutPort do[3:0] { Source dataM[3:0] ; }

      ScanInterface cA12 {
         Port se1; Port ce1; Port ue1;
         Chain c1 { Port siA; Port so ; }
      }

      ScanInterface cB12 {
         Port se2; Port ce2; Port ue2;
         Chain c1 { Port siB; Port so ; }
      }

      ScanRegister regA[7:0] {
         ScanInSource siA ;
         ResetValue   8'b0 ;
      }

      ScanRegister regB[7:0] {
         ScanInSource siB ;
         ResetValue   8'b0 ;
      }

      ScanMux scanM SelectedBy dselA {
         1'b0 : regA[0] ;
         1'b1 : regB[0] ;
      }

      ClockMux clockM SelectedBy dselA {
         1'b0 : clkA ;
         1'b1 : clkB ;
      }

      DataMux dataM[3:0] SelectedBy dselB[2:0] {
         3'bx00 : regA[7:4] ;
         3'bx01 : regA[3:0] ;
         3'bx1x : regB[5:2] ;
      }
   }
```

ScanMux ClockMux

ClockMux

Syntax

```
Module module_name {
  ClockMux mux_name SelectedBy mux_select_signal {
    mux_select_value : clock_source_name ;
  }
}
```

Description

The ClockMux statement creates and names a clock multiplexor.

IEEE P1687 differentiates between a scan multiplexor, a data multiplexor, and a clock multiplexor. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexor only switches between scan signals, the data multiplexor only switches between data signals, and the clock multiplexor only switches between clock signals. No signal types may be mixed for any of the multiplexors. The select signal of the multiplexors may be sourced only by data signals.

Parameters

- *mux_name*

  A string that identifies the name of a data multiplexor of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: ScanRegister, DataRegister, ScanMux, DataMux, OneHotDataGroup, OneHotScanGroup, LogicSignal, Alias.

  Using this name, the outgoing signal of the multiplexor can be referenced. The width of *mux_name* must match the with of the *clock_source_name*.

- *mux_select_value* : *clock_source_name*

  A repeatable string-string pair, connected by a colon symbol ':'. A DataMux must have at least one *mux_select_value* - *clock_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

  The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *clock_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Example

The following shows usages of all the multiplexor types.

```
Module chip2 {
   ScanInPort  siA ;
   ScanInPort  siB ;
   ScanOutPort so      { Source scanM ; }

   ShiftEnPort   se1 ;
```

```

ScanMux DataMux

OneHotDataGroup

Syntax

```
Module module_name {
  OneHotDataGroup onehotdatagroup_name {
    Instance ;
    DataRegister ;
    Port concat_signal ;
  }
}
```

Description

The OneHotDataGroup statement implements a convenient way of declaring a named, hierarchically distributed data multiplexor. You would use a OneHotDataGroup if various inputs to the multiplexor are sourced by data registers distributed across multiple instances. This statement simplifies the declaration of such a data multiplexor by automatically making the correct data input and data output connections, including read, write, and address connections.

A OneHotDataGroup may use any combination of the three options declaring the source input signal of the multiplexor. The order of the declarations is not relevant, since each source should have an enable signal defined in such a way that at most one source is selected at a time. The OneHotDataGroup then assumes the value of this selected, unique source, or the x-value, if none of the sources is selected, or if multiple data sources are selected simultaneously.

Parameters

- *onehotdatagroup_name*

  A required string, declaring the name of the OneHotDataGroup. This name can be considered as the name of the distributed multiplexor. As usual, *onehotdatagroup_name* can be used to refer to the output signal of this multiplexor, for example as a source of a DataOutPort statement. The width of *onehotdatagroup_name* must be larger or equal to the width of the connected output ports of the referenced Instance or DataRegister. *onehotdatagroup_name* assumes the value of the one selected source, or the x-value, if none of its sources are enabled.

- Instance

  An optional, repeatable Instance statement. This instance must use the AddressValue parameter.

- DataRegister

  An optional, repeatable DataRegister statement. This DataRegister must use the AddressValue parameter.

- Port *concat_signal*

  An optional, repeatable keyword-string pair. *concat_signal* may reference a data output single signal or a concatenation of such signals. *concat_signal* may also be a hierarchical instance pathname ending at a data source signal. The referenced signal will be considered an input port of the multiplexor represented by the OneHotDataGroup statement. For the

enable signal required for each source of the OneHotDataGroup's source signal, one of the following rules will apply:

- For a referenced DataOutPort, the Enable statement is included in the DataOutPort declaration.
- For a referenced DataOutPort, the Source parameter references another data signal, which has an enabling condition.
- The instance referenced in the instance pathname in a hierarchical *concat_signal* has an AddressValue parameter.
- A primary input port of the top level module is assumed to have an enabling condition from the outside.

Example

The following shows an example of a OneHotDataGroup. Observe how the address of a DataRegister is determined. For example the DataRegister with the hierarchical name phy1.bank1.D1 has the address of 8'b01 000000 + 6'b0001 00 + 2'b01 = 8'b01 0001 01. Similarly, the DataRegister phy2.R has the address 8'b10 000000 + 6'b0010 00 = 8'b10 0010 00.

The Example 2 of the Instance statement shows a variation of this example.

```
Module tap {Module top {
   AddressPort   address[7:0] ;
   DataInPort    dataIn[15:0] ;

   DataInPort    write_enable ;
   DataInPort    read_enable ;

   DataOutPort   dataOut[15:0] { Source outMux[15:0] ; }

   OneHotDataGroup outMux[15:0] {
     Instance phy1 Of phy {
       AddressValue 2'b01, 6'b000000 ;
       InputPort we = write_enable ;
       InputPort re = read_enable ;
     }

     Instance phy2 Of phy {
       AddressValue 2'b10, 6'b000000 ;
       InputPort we = write_enable ;
       InputPort re = read_enable ;
     }
   }
}

Module phy {
   DataInPort    dataIn1[7:0] ;
   DataInPort    dataIn2[7:0] ;

   WriteEnPort   we ;
   ReadEnPort    re ;
   AddressPort   address1[3:0] ;
```

```
      AddressPort   address2[3:0] ;

      DataOutPort   dataOut[15:0] { Source outMux[15:0] ; }

      OneHotDataGroup outMux[15:0] {

        DataRegister R[15:0] {
          AddressValue 4'b0010,2'b00 ;
        }

        Instance bank1 Of bank {
          AddressValue 4'b0001,2'b00 ;
        }
      }
   }

   Module bank {
      DataInPort    dataIn[15:0];

      WriteEnPort   we ;
      ReadEnPort    re ;
      AddressPort   address[1:0];

      DataOutPort   dataOut[15:0] { Source outMux[15:0] ; }

      OneHotDataGroup outMux[15:0] {
//    AddressValue 2'bx,4'bx,2'b<num>
        DataRegister D0[15:0] { AddressValue 2'b00 ; }
        DataRegister D1[15:0] { AddressValue 2'b01 ; }
        DataRegister D2[15:0] { AddressValue 2'b10 ; }
        DataRegister D3[15:0] { AddressValue 2'b11 ; }
      }
   }
```

Instance
DataRegister
OneHotScanGroup

OneHotScanGroup

Syntax

```
Module module_name {
  OneHotScanGroup onehotscangroup_name {
    Port source_name ;
  }
}
```

Description

The OneHotScanGroup statement implements a convenient way of declaring a named, hierarchically distributed scan multiplexor. You would use a OneHotScanGroup if various inputs to the multiplexor are sourced by scan-out ports distributed across multiple instances. This statement simplifies the declaration of such a scan multiplexor by automatically making the correct scan input and scan output connections.

Parameters

- *onehotscangroup_name*

  A required string, declaring the name of the OneHotScanGroup. This name can be considered as the name of the distributed multiplexor. As usual, *onehotscangroup_name* can be used to refer to the output signal of this multiplexor, for example as a source of a ScanOutPort statement. The width of *source_name* must be equal to the width of *onehotdatagroup_name*. Each scan source must have an enable signal defined in such a way that at most one source is selected at a time when the OneHotScanGroup is in the active scan path. This enable signal is not necessarily directly at the ScanOutPort of *source_name*, but might be located deeper in the hierarchy, for example, through cascaded OneHotScanGroups. When selected, the *onehotdatagroup_name* then assumes the value of this selected source, or the x-value, if none of the sources is selected, or multiple sources would had been selected.

- Port *source_name*

  A required, repeatable keyword-string pair. *source_name* may reference a scan output port single signal or a concatenation of such signals. *source_name* may also be a hierarchical instance pathname ending at a scan output port signal. The referenced scan output port signals will be considered an input port of the multiplexor represented by the OneHotScanGroup statement.

Example

The following shows a example of a OneHotScanGroup. Observe how easy it is to declare the hierarchically distributed scan multiplexor “outScanMux” and the usage of the OneHotScanGroup’s name in the Source statement of the top level scan-out port.

```
Module chip_onehotscangroup {
   ScanInPort       si;
   ScanOutPort      so       { Source outScanMux; }
   ShiftEnPort      se;
   SelectPort       en[3:0];
```

```
      CaptureEnPort    ce;
      UpdateEnPort     ue;
      TCKPort          tck;

      OneHotScanGroup outScanMux {
        Port tdr_0.so ;
        Port tdr_1.so ;
        Port tdr_2.so ;
        Port tdr_3.so ;
      }

      Instance tdr_0 Of tdr {
        InputPort si = si ;
        InputPort en = en[0];
      }
      Instance tdr_1 Of tdr {
        InputPort si = si ;
        InputPort en = en[1];
      }
      Instance tdr_2 Of tdr {
        InputPort si = si ;
        InputPort en = en[2];
      }
      Instance tdr_3 Of tdr {
        InputPort si = si ;
        InputPort en = en[3];
      }
   }

   Module tdr {

      ScanInPort       si;
      ScanOutPort      so       { Source R[0]; Enable en; }
      ShiftEnPort      se;
      SelectPort       en;
      CaptureEnPort    ce;
      UpdateEnPort     ue;
      TCKPort          tck;

      ScanRegister R[7:0] {
         ScanInSource     si;
         ResetValue       8'b0 ;
      }
   }
```

AccessLink

Syntax

```
Module module_name {
  AccessLink instance_name Of STD_1149_1_2001 {
    BSDLEntity entity_name;
    intruction_name {
      ScanInterface { scan_interface_name; ...} //mandatory
      ActiveSignals { signal_name; ...} //optional
    }
  }
}
```

Description

A wrapper that can be used inside the top level ICL Module to link an ICL network to an 1149.1 TAP controller that is described in a BSDL file. The tool currently only supports the BSDL format that is part of IEEE1149.1-2001.

When reading an ICL file which contains an ICL module with an AccessLink Of STD_1149_1_2001, the read_icl command must be used with the -bsdl_file option to provide the path to the referenced BSDLEntity. An error is generated if the specified BSDLEntity is not found in the specified BSDL file.

Parameters

- *instance_name*

  A string used to define the instance name of the AccessLink. The string must start with a letter and only contain letters, numbers and underscores. As shown in the Example below, the *instance_name* is used when refering to the defined *signal_name* in an ICL connection. When the AccessLink is read in the tool, a TAP ICL module is created from the BSDL and instantiated in the top level ICL module in place of the AccessLink using the same *instance_name*. This is also illustrated in the Example below.

- BSDLEntity entity_name;

  A required keyword-string pair which defines the name of the BSDL entity that is referenced by the AccessLink wrapper. The file pointed to by the “read_icl -bsdl_file” option must contain an “Entity *entity_name* is” clause.

- *instruction_name*

  A required string that references one of the instruction names defined in the INSTRUCTION_OPCODE attribute of the BSDL file. When the specified instruction_name is loaded in the INSTRUCTION register, the scan_interface_names listed in the ScanInterface wrapper are placed along the active DR scan path between the TAP_SCAN_IN and TAP_SCAN_OUT ports.

- scan_interface_name

  A repeatable string that references the ScanInterface of ICL module instances. The format of the string is a *leaf_instance_name* followed by an optional “.*scan_interface_name*”

string. The "*.scan_interface_name*" string is optional when the ICL module associated with the *leaf_instance_name* only has one ScanInterface. If the ICL module associated to the *leaf_instance_name* has more than one ScanInterface wrappers, the "*.scan_interface_name*" string is mandatory to identify one of them.

The *scan_interface_name* are serially daisy chained with the first one closer to TDI and the last one closer to TDO.

- signal_name

  A repeatable string that defines signal_names that are high when the *instruction_name* is loaded into the INSTRUCTION register. When a signal_name is not specified inside a given *instruction_name* wrapper, the signal is low when the *instruction_name* is loaded into the INSTRUCTION register. The signal_names are identified as "*instance_name.signal_name*" when refrenced to make connections in the ICL. This is illustrated in the Example below.

Example

Below is an example of a top level ICL module containing an AccessLink. It references a BSDL file which contains the element shown below. After the elaboration which is triggered by the set_current_design command, you can see that a TAP controller was extracted from the BSDL file and instantiated into the top level ICL module. The TAP ports were also extracted and added to the ICL module. The original AccessLink wrapper is commented out. The ClockPorts and their original connections are left unaffected.

Note

If an ICL module with an AccessLink statement has been loaded into memory by means of read_icl, then the commands write_icl and report_icl_modules do not result in usable ICL of this module before it has been subject to set_current_design.

Following is the content of mydesign.icl with an AccessLink wrapper. Notice how the ActiveSignal long_setup is referenced as "bsdl_tap.long_setup" when used to connect the "selectWIR" input port of the "core" instance.

```
Module mydesign {
  ClockPort CLK;
  AccessLink bsdl_tap Of STD_1149_1_2001 {
    BSDLEntity acme4523;
    BP0_LONG_SETUP {
      ScanInterface {core.ijtag0;}
      ActiveSignals {long_setup;}
    }
    BP0_SHORT_SETUP {
      ScanInterface {core.ijtag0;}
    }
    BP1_LONG_SETUP {
      ScanInterface {core.ijtag1;}
      ActiveSignals {long_setup;}
    }
    BP1_SHORT_SETUP {
      ScanInterface {core.ijtag1;}
```

```
      }
    }

    Instance core Of core {
      InputPort selectWIR = bsdl_tap.long_setup;
      InputPort clk = CLK;
    }

  }
```

Following is the section from the BSDL file “acme4523.bsdl” that is used to extract the TAP controller.

```
entity acme4523 is
   attribute TAP_SCAN_RESET of TRST : signal is true;
   attribute TAP_SCAN_IN    of TDI  : signal is true;
   attribute TAP_SCAN_MODE  of TMS  : signal is true;
   attribute TAP_SCAN_OUT   of TDO  : signal is true;
   attribute TAP_SCAN_CLOCK of TCK  : signal is (1.0e+07, BOTH);

attribute INSTRUCTION_OPCODE of TOP: entity is
      "IDCODE           (111111111111111110)," &
      "BYPASS           (111111111111111111)," &
      "EXTEST           (111111111111101000)," &
      "SAMPLE           (111111111111111000)," &
      "PRELOAD          (111111111111111000)," &
      "CLAMP            (111111111111101111) " &
      "BP0_LONG_SETUP   (XXXXXX000111XXX010)," &
      "BP1_LONG_SETUP   (XXXXXX001101XXX010)," &
      "BP2_LONG_SETUP   (XXXXXX001001XXX010)," &
      "BP3_LONG_SETUP   (XXXXXX000101XXX010)," &
      "BP4_LONG_SETUP   (XXXXXX000001XXX010)," &
      "BP0_SHORT_SETUP  (XXXXXX110110XXX010)," &
      "BP1_SHORT_SETUP  (XXXXXX111100XXX010)," &
      "BP2_SHORT_SETUP  (XXXXXX111000XXX010)," &
      "BP3_SHORT_SETUP  (XXXXXX110100XXX010)," &
      "BP4_SHORT_SETUP  (XXXXXX110000XXX010) " ;

end acme4523;
```

Below is a dofile that loads the ICL modules in memory and elaborates them. The modified top level ICL module as well as the created TAP ICL modules are then reported. Notice how the TAP ICL module is called <bsdl_entity_name>_bsdl_tap. Its leaf instance name reused the one that was used by the AccessLink.

```

read_icl

NameSpace

Syntax

```
NameSpace space_name ;
Module module_name { ... }
```

Description

A NameSpace statement is used to place all subsequent modules in a specific namespace.

This namespace prevents module name collisions, for example, between different vendors, each offering a MemoryBIST module. Each vendor may, for example, use their company name as the namespace, thus avoiding a module name collision.

To reference a particular module, you can either use the UseNameSpace statement or prefix the namespace name before the module name.

Example

```
NameSpace VendorA ;
Module MBIST ;

NameSpace VendorB ;
Module MBIST
```

Then later, you can use, for example:

```
Instance MBIST_inst Of VendorA::MBIST
UseNameSpace VendorB
Instance MBIST_inst Of MBIST
```

Note

Currently Tessent does not support the NameSpace statement.

Related Topics

UseNameSpace

UseNameSpace

Syntax

```
UseNameSpace space_name ;
Module module_name { ... }
```

Description

A UseNameSpace statement is used to reference all subsequent modules from a specific namespace defined earlier through the NameSpace statement.

To reference a particular module, you can either use the UseNameSpace statement or prefix the namespace name before the module name.

Example

```
NameSpace VendorA ;
Module MBIST ;

NameSpace VendorB ;
Module MBIST
```

Then later, you can use, for example:

```
Instance MBIST_inst Of VendorA::MBIST
UseNameSpace VendorB
Instance MBIST_inst Of MBIST
```

Note

Currently Tessent does not support the UseNameSpace statement.

Chapter 7
Command Dictionary

This chapter describes the Tessent Shell commands. For quick reference, the commands appear alphabetically with each beginning on a separate page.

Command Line Syntax Conventions

This manual uses the following command usage line syntax conventions.

Table 7-1. Conventions for Command Line Syntax

Convention	Example	Usage
UPPercase	-STatic	Required argument letters are in uppercase; in most cases, you may omit lowercase letters when entering literal arguments, and you need not enter in uppercase. Arguments are normally case insensitive.
Boldface	set_fault_mode **<u>Uncollapsed</u>** | **Collapsed**	A boldface font indicates a required argument.
[ ]	exit [-force]	Square brackets enclose optional arguments. Do not enter the brackets.
Italic	dofile ***filename***	An italic font indicates a user-supplied argument.
{ }	add_ambiguous_paths {***path_name*** | **-All**} [-Max_paths *number*]	Braces enclose arguments to show grouping. Do not enter the braces.
|	add_ambiguous_paths {***path_name*** | **-All**} [-Max_paths *number*]	The vertical bar indicates an either/or choice between items. Do not include the bar in the command.
Underline	set_dofile_abort **<u>ON</u>** | **OFf**	An underlined item indicates either the default argument or the default value of an argument.
…	add_clocks ***off_state primary_input_pin***… [-Internal]	An ellipsis follows an argument that may appear more than once. Do not include the ellipsis when entering commands.

Command Summary

Table 7-2 contains a summary of the commands described in this manual. For the list of contexts and system modes in which command is available, refer to the command's reference page.

Table 7-2. Command Summary

Command	Description
add_ambiguous_paths	Specifies to derive multiple paths from ambiguous paths when there is path or edge ambiguity.
add_atpg_constraints	Restricts all patterns placed into the internal pattern set according to the user-defined constraints.
add_atpg_functions	Creates an ATPG function that you can then use when generating user-defined ATPG constraints.
add_bist_capture_range	Associates a named ATPG capture procedure with a subset of the BIST patterns.
add_black_boxes	Defines instances of Verilog modules or ATPG library models as black boxes for ATPG and sets the constrained value on output or bidirectional black box pins.
add_browser_data	Adds the specified data to the active tab of the DFTVisualizer Browser window.
add_capture_handling	Specifies the data capturing behavior for the given state element.
add_cdp_test	Creates a new test in the CDP. The test is based on the specified pattern file.
add_cell_constraints	Constrains scan cells (also non-scan cells for CX, TX, DX, and SX constraints) to a constant value.
add_cell_models	Specifies DFT library models for user-defined test points, system-generated test points, and system-generated test logic.
add_chain_masks	Masks the load, capture, and/or unload values on the specified scan chains during simulation.
add_clocks	Adds scan or non-scan clock pins to the clock list for proper scan operation. Any signal is considered to be a clock if it can change the state of a sequential element, including system clocks, sets, and resets.
add_config_element	Adds a configuration element in the configuration tree.

Table 7-2. Command Summary (cont.)

Command	Description
add_config_message	Adds error, warning, or information messages to configuration elements.
add_config_tab	Adds one or many configuration tree tabs in the DFTVisualizer Configuration Data window.
add_control_points	Specifies user-defined control points during test point insertion.
add_core_instances	Adds a core instance to the design by associating/binding the core description currently in memory with the specified core instance(s) in the design.
add_display_data	Adds specified data columns to the Data window of DFTVisualizer, opening the Data window if it is not already open. If data corresponding to an added column is available, it is displayed.
add_display_instances	Displays instances in DFTVisualizer and enables you to trace visually through the design using the Debug or Design window.
add_edt_blocks	Creates an arbitrary identifier for an EDT block and applies certain subsequent commands only to that block.
add_edt_configurations	Sets up EDT logic with two compression configurations.
add_edt_connections	Specifies EDT logic connections for the block-level design flow.
add_false_paths	Defines false paths in the design. False paths are paths that cannot be activated in the design's functional (at-speed) mode of operation. You would typically determine them as a part of static timing analysis, prior to ATPG.
add_fault_sites	Automatically adds fault site definitions for library cells that don't have UDFM definitions.
add_faults	Adds faults to the current fault list, discards all patterns in the current test pattern set, and sets all faults to undetected (actual category is UC).
add_icl_ports	Specifies top design ports that will be added as DataInPort or DataOutPort ports in the ICL file generated during ICL extraction.
add_icl_scan_interfaces	Adds the specified scan interfaces to the new ICL top module that will be created during ICL extraction.

Table 7-2. Command Summary (cont.)

Command	Description
add_iddq_exceptions	Enables you to specify individual sites where the tool does not apply the Iddq restrictions.
add_input_constraints	Constrains primary inputs to specified values.
add_lfsr_connections	Connects an external pin or an internal pin to a Linear Feedback Shift Register (LFSR).
add_lfsr_taps	Adds the tap configuration to a Linear Feedback Shift Register (LFSR) or a PRPG of type cellular automata (CA).
add_lfsrs	Adds LFSRs for use as PRPGs or MISRs.
add_lists	Adds pins to the list of pins on which to report.
add_misrs	Specifies the MISR structure and initial seed.
add_nofaults	Places nofault settings either on pin pathnames, pin names of specified instances, or modules.
add_nonscan_instances	Marks specific sequential elements for exclusion from the scan insertion process.
add_nonscan_models	Instructs the tool to ignore all instances of the specified sequential DFT library model when identifying and inserting the required scan elements and test logic into the design.
add_norace_clocks	Defines one or more non-interacting clocks.
add_notest_points	Adds circuit points to the list for exclusion from testability insertion.
add_observe_points	Specifies user-defined observe points during test point insertion.
add_output_masks	Ignores any fault effects that propagate to the primary output pins you name.
add_primary_inputs	Adds a primary input (PI) to the specified nets or pins.
add_primary_outputs	Adds primary outputs to the specified net.
add_processors	Enables the tool to run multiple processes in parallel on multiple machines to reduce runtime.
add_read_controls	Adds an off-state value to specified RAM read control lines.

Table 7-2. Command Summary (cont.)

Command	Description
add_register_value	Creates a static or dynamic variable by allowing you to specify a register identifier, value_name, and, optionally, the state string, value_string.
add_scan_chains	Specifies a name for a pre-existing scan chain within the design.
add_scan_groups	Specifies a group name for a set of pre-existing scan chains in a design. Only one group name can be specified per session.
add_scan_instances	Adds specified instances to the scannable instance list.
add_scan_models	Specifies that the tool is to flag every instance of the named DFT library model for inclusion into the identified scan list.
add_scan_partition	Specifies a grouping of scan cells (a partition) in which scan chains are inserted separately from the remaining scan cells in the design.
add_scan_pins	Declares the name of a scan chain at the top-level module and assigns the corresponding scan input pin, scan output pin, and optionally, scan clock pin you associate with the chain.
add_simdut_fault	Injects a stuck-at-0 fault or a stuck-at-1 fault into the specified signal for SimDUT simulation.
add_simulation_context	Creates a new user-defined simulation context.
add_simulation_force	Forces one or more gate_pin objects to the specified value.
add_sub_chains	Specifies a pre-existing scan chain (subchain) within a module, library model, instance, blackbox, or empty module in a hierarchical design to be stitched into the top-level scan chain during the stitching process.
add_subchain_clocks	Specifies the clock pins for scan chains within modules, library models, instances, blackboxes, or empty modules of a hierarchical design.
add_subchain_group	Adds one subchain group to the system.
add_tied_signals	Adds a value to floating signals or pins.
add_to_collection	Adds objects to a base collection and returns the new collection without affecting the original base collection.
add_write_controls	Specifies the off-state value of the write control lines for RAMs.

Table 7-2. Command Summary (cont.)

Command	Description
analyze_atpg_constraints	Checks the ATPG constraints you created for their satisfiability or mutual exclusivity.
analyze_bus	Analyzes the specified bus gates for contention problems.
analyze_compression	Analyzes the compression for an application in two steps.
analyze_control_signals	Identifies and optionally defines the primary inputs of control signals.
analyze_drc_violation	Generates a schematic in the Debug window of the portion of the design involved with the specified rule violation number.
analyze_fault	Performs an analysis to identify why a fault is not detected and optionally displays the relevant circuitry in DFTVisualizer.
analyze_graybox	Identifies the instances and nets to be included in the graybox netlist by automatically setting their in_graybox attributes to “true”. Subsequently, a “write_design -graybox” command writes out the graybox netlist for the marked instances and nets.
analyze_restrictions	Performs an analysis to automatically determine sources of the problem from a failed ATPG run.
analyze_simulation_mismatches	Analyzes simulation mismatches that occur between test patterns and a simulation performed by a specified external timing simulator.
analyze_test_points	Performs X-bounding analysis.
analyze_wrapper_cells	Identifies shared and dedicated wrapper cells for the primary I/O ports.
analyze_xbounding	Performs X-bounding analysis.
annotate_diagnosis	Adds DFM and RCD data, if available, to existing diagnosis reports.
append_to_collection	Adds one or more objects to a collection referenced by the specified var_name.
apply_specification_defaults	Automatically applies all defaults specified in the DefaultSpecification/DftSpecification wrappers to the DftSpecification wrappers that were created manually.

Table 7-2. Command Summary (cont.)

Command	Description
catch_output	Executes the specified tool command line, and may be used to prevent command errors from aborting the enclosing dofile or Tcl proc.
close_layout	**Layout-Aware Diagnosis Flow:** Closes the Layout Database. Any subsequent diagnosis you perform is non-layout aware. **SVDB Layout Marker Flow:** Releases the Calibre Query Server and closes the layout. If you issue this command, then the tool no longer generates layout markers.
close_pattern_set	Finalizes and closes the currently open pattern_set.
close_tsdb	Makes the content of previously opened TSDB directory invisible to the tool.
close_visualizer	Saves display data and closes DFTVisualizer.
compare_collections	Compares the contents of two collections.
compress_layout	Compresses a Layout Database.
compress_patterns	Compresses patterns in the current test pattern set.
copy_collection	Duplicates the contents of an existing collection, resulting in a new collection. The base collection remains unchanged.
copy_module	Creates an exact copy of a design module and assigns it a new name so that it can then be used as part of a create_instance and replace_instances.
copy_simulation_context	Copies the simulation values and forces from one simulation context to another.
create_capture_procedures	Creates named capture procedures based on clock sequences either derived from patterns or specified at the command line.
create_connections	Connects pin, net, or port objects.
create_dft_specification	Creates the “DftSpecification(design_name,id)” configuration wrapper and returns the newly created wrapper object so that it can be stored in a variable and used to customize the created specification.
create_diagnosis_patterns	Creates targeted patterns for logic failure or scan chain failure iterative diagnosis.

Table 7-2. Command Summary (cont.)

Command	Description
create_flat_model	Creates a primitive gate simulation representation of the design. The command also flattens the hierarchy of the design so that the design can be viewed in the DFTVisualizer debug window.
create_initialization_patterns	Creates RAM initialization patterns and places them in the internal pattern set.
create_instance	Instantiates an instance of a module mod_spec inside a design module in the current design.
create_layout	Generates a diagnosis tool-compatible Layout Database directory from LEF/DEF input files.
create_module	Creates a new design module with no ports.
create_net	Creates a net inside an instance of a design module in the current design.
create_patterns	Performs automatic high-speed test generation and pattern compression.
create_pin	Creates a pin on an instance of a design module.
create_port	Creates a port on the specified design module.
delete_atpg_constraints	Removes state restrictions from the specified pins. You define pin restrictions by using the add_atpg_constraints command.
delete_atpg_functions	Removes the specified function definitions.
delete_bist_capture_ranges	Specifies that the tool no longer uses a particular named capture procedure when generating BIST patterns.
delete_black_boxes	Undoes the effect of the add_black_boxes command.
delete_browser_data	Removes data from the active tab of the DFTVisualizer Browser window.
delete_capture_handling	Removes the special data capture handling for the specified objects.
delete_capture_procedures	Removes the specified capture procedures from internal memory.
delete_cdp_test	Deletes a test and its associated test patterns from the CDP.
delete_cell_constraints	Removes constraints placed on scan cells.

Table 7-2. Command Summary (cont.)

Command	Description
delete_cell_library	Removes all current cell libraries, the current design including the flattened model, and all tool data that is design-specific.
delete_cell_models	Specifies the name of the DFT library cell that the tool is to remove from the active list of cells that the user can access when adding test points or that the tool can access when inserting test logic.
delete_chain_masks	Removes chain masks from the specified scan chains.
delete_clocks	Removes primary input pins from the clock list.
delete_config_elements	Deletes one or more configuration elements. Only elements which can be added can be deleted.
delete_config_messages	Deletes error, warning or info message that were added to configuration elements using the add_config_message command.
delete_config_tabs	Deletes one or many configuration tree tabs from the Configuration Data window that was previously added using add_config_tab or display_specification.
delete_connections	Disconnects net, pin, or port objects.
delete_core_descriptions	Removes core descriptions that have been read in using the read_core_descriptions command from memory.
delete_core_instances	Removes an instance binding created with the add_core_instances command.
delete_design	Removes the current design including the flattened model, and all tool data that is design-specific.
delete_dfm	Deletes all the DFM rules from the open VDB.
delete_display_data	Removes a data column from the DFTVisualizer Data window.
delete_display_instances	Removes the specified design instances from a DFTVisualizer display window.
delete_edt_blocks	Removes the data for the specified EDT block(s) from the tool's internal database.
delete_edt_configurations	Deletes specified compression configurations from all blocks in a design.

Table 7-2. Command Summary (cont.)

Command	Description
delete_edt_connections	Deletes connections previously specified with the add_edt_connections command.
delete_false_paths	Removes definitions of false paths.
delete_fault_sites	Removes bridge entries, delay paths, user-defined fault sites, and any associated faults from the current fault list. For UDFMs, all faults are removed.
delete_faults	Removes faults from the current fault list.
delete_flat_model	Deletes a flat model that was previously created either by going to system mode analysis or by using the create_flat_model command.
delete_icl_modules	Deletes the specified ICL modules from memory.
delete_icl_ports	Undoes the effect of the add_icl_ports command on a specified list of top level ports.
delete_iddq_exceptions	Deletes exceptions to Iddq restrictions added with the add_iddq_exceptions command.
delete_input_constraints	Removes previously applied constraints from primary input pins.
delete_instances	Deletes the specified instance objects from the current design.
delete_iproc	Deletes the specified list of iProcs attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.
delete_layout_verification	Reports or deletes stored layout verification information from the current layout database.
delete_lfsr_connections	Removes connections between the specified primary pins and Linear Feedback Shift Registers (LFSRs).
delete_lfsr_taps	Removes the tap positions from a Linear Feedback Shift Register (LFSR).
delete_lfsrs	Removes the specified Linear Feedback Shift Registers (LFSRs).
delete_lists	Removes pins from the pin list the tool monitors and reports on during simulation.
delete_misrs	Deletes MISRs you specify with the add_misrs command.

Table 7-2. Command Summary (cont.)

Command	Description
delete_multicycle_paths	Removes definitions of multicycle paths previously read in using the read_sdc command.
delete_nets	Removes net objects inside an instance of a design module.
delete_nofaults	Removes the nofault settings from either the specified pin or instance/module pathnames.
delete_nonscan_instances	Removes the specified sequential instances from the non-scan instance list.
delete_nonscan_models	Removes from the non-scan model list the specified sequential DFT library models.
delete_norace_clocks	Removes clocks from user-defined non-interacting clock domains.
delete_notest_points	Removes the circuit point which the tool cannot use for testability insertion from the specified pins.
delete_output_masks	Removes the masking of the specified primary output pins.
delete_patterns	Deletes the current pattern set.
delete_pins	Removes pin objects from a design module instance.
delete_ports	Removes port objects from a design module.
delete_primary_inputs	Removes the specified primary inputs from the existing flattened model or, if a flattened model does not yet exist, from the flattened result.
delete_primary_outputs	Removes the specified primary outputs from the existing flattened model or, if a flattened model does not yet exist, from the flattened result.
delete_processors	Removes processor definitions previously specified with the add_processors command.
delete_read_controls	Removes the read control line definitions from the specified primary input pins.
delete_register_value	Deletes all or a specified register value variable specified with the add_register_value command.
delete_scan_chains	Removes the specified scan chain definitions from the scan chain list.
delete_scan_groups	Removes the specified scan chain group definitions from the scan chain group list.

Table 7-2. Command Summary (cont.)

Command	Description
delete_scan_instances	Removes the specified, sequential instances from the user-identified scan instance list.
delete_scan_models	Removes the specified sequential models from the scan model list.
delete_scan_partitions	Deletes the user-specified scan partitions.
delete_scan_pins	Removes any previously assigned scan input, output, and clock names from the specified scan chains.
delete_simdut_fault	Removes the injected stuck-at fault at the specified signal.
delete_simulation_contexts	Deletes one or more user-defined simulation contexts.
delete_simulation_forces	Removes forces from one or more gate_pin objects.
delete_sub_chains	Removes scan subchains previously defined with the add_sub_chains command. Use the report_sub_chains command to display the currently defined scan subchains.
delete_subchain_clocks	Deletes subchain clocks previously defined with the add_subchain_clocks command.
delete_subchain_groups	Removes a scan subchain group.
delete_test_points	Removes the specified test point definitions.
delete_tied_signals	Removes the assigned (tied) value from the specified floating nets or pins.
delete_write_controls	Removes the write control line definitions from the specified primary input pins.
display_specification	Displays the DftSpecification(design_name,id) configuration data in a tab of the Configuration Tree window of DFTVisualizer.
diagnose_failures	Diagnoses the failures in the specified failure file.
display_specification	Displays the DftSpecification(design_name,id) configuration data in a tab of the Configuration Tree window of DFTVisualizer.
display_diagnosis_report	Opens a diagnosis report in which you can click symptoms and suspect locations to add related gates to the DFTVisualizer Debug window.
display_message	Sends a message to the specified message stream.

Table 7-2. Command Summary (cont.)

Command	Description
dofile	Executes the commands contained within the specified file.
echo	Issues a user-defined string to the transcript.
execute_cdp_test	Executes the specified test using the currently connected tester.
execute_gpib_command	Allows you to control and program GPIB equipment.
exit	Terminates the application tool program.
expand_compressed_patterns	Expands compressed 1-hot patterns for better internal failing flop diagnosis.
extract_icl	Checks the ICL connectivity rules between Ijtag instances and extracts the top-level ICL module.
filter_collection	Filters a previously created collection, resulting in a new collection.
find_design_names	Displays design object hierarchical names matched by an input string, which may include asterisk (*) or question mark (?) wildcard characters.
foreach_in_collection	Iterates over each element in a collection.
get_attribute_list	Returns an alphabetically sorted Tcl list of attribute names.
get_attribute_option	Retrieves the current setting of an attribute's option.
get_attribute_value_list	Retrieves the value of an attribute on the specified design objects.
get_cdp_test_list	Returns a Tcl list of tests currently available in the CDP.
get_clock_list	Returns a list of all clocks specified with the add_clocks command.
get_clock_option	Returns the setting of an option specified with the add_clocks command.
get_common_parent_instance	Returns the common ancestor of all instances, pins, or nets found in object_spec.
get_config_elements	Returns a collection of configuration elements or a count of configuration elements when the -count option is used.
get_config_messages	Returns a list of message strings attached to a configuration element.

Table 7-2. Command Summary (cont.)

Command	Description
get_config_selected_nodes	Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data window.
get_config_value	Returns different values associated with a configuration element based on the specified option.
get_context	Introspects the current context.
get_current_design	Returns a collection of one element that specifies the top-level design when previously set.
get_current_mode	Returns the current mode as specified by the set_current_mode command.
get_current_simulation_context	Returns the name of the current simulation context.
get_design_level	Returns the design level previously defined with the set_design_level command.
get_design_sources	Returns the pathnames or file extensions previously specified with the set_design_sources command.
get_dfm_rules	Returns a TCL list of the DFM rules contained in the layout database.
get_dft_cell	Retrieves the named sets of cells to use when test hardware must be inserted (as a Tcl list of the currently available cell selection names), or a particular cell given the name and desired cell function of a specified set of cells.
get_fanins	Returns a collection of all requested objects found in the fanin of the specified pin, net, or port object.
get_fanouts	Returns a collection of all requested objects found in the fanout of the specified pin, net, or port object.
get_fault_type	Returns the current fault model type, as previously specified by the set_fault_type command.
get_gate_pins	Returns a collection of gate_pin objects found below the current design in the flat model.
get_icl_extraction_options	Provides access to the settings specified by the set_icl_extraction_options command.
get_icl_fanins	Returns a collection of all requested objects found in the fanin of the specified pin or port objects.

Table 7-2. Command Summary (cont.)

Command	Description
get_icl_fanouts	Returns a collection of all requested objects found in the fanout of the specified ICL pin, or port objects.
get_icl_instances	Returns a collection of all ICL instances instantiated relative to the current design that match the specified *name_patterns list or -filter expression.
get_icl_modules	Returns a collection of all ICL modules that match the specified name_patterns list or -filter expression.
get_icl_pins	Returns a collection of all hierarchical ICL pins instantiated relative to the current design that match the specified name_patterns list or -filter expression.
get_icl_ports	Returns a collection of all ports on a given module that match the specified name_patterns list or -filter expression.
get_icl_scope	Introspects the current ICL scope.
get_iclock_list	Returns a list of ICL port and pin names on which you have issued an iClock command.
get_iclock_option	Returns the effective or specified source, frequency multiplier, frequency divider, or clock period values for the specified icl_port_or_pin_name.
get_ijtag_instances	Returns the design level previously defined with the set_design_level command.
get_ijtag_instance_option	Returns the value of the selected option for the specified Ijtag instance.
get_ijtag_retargeting_options	Returns the value of the specified option of the previous set_ijtag_retargeting_options command or its default value if the set_ijtag_retargeting_options command was not issued.
get_insertion_option	Returns the value of any insertion option that is specifiable with the set_insertion_options command.
get_insert_test_logic_options	Retrieves the current prefix that will be used when creating test point logic.
get_instances	Returns a collection of all instances instantiated relative to the current design that match the specified name_patterns list, subject to filtering imposed by the other optional options.

Table 7-2. Command Summary (cont.)

Command	Description
get_iproc_argument_default	Returns the default value for the specified arg_name of the specified proc_name attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.
get_iproc_argument_list	Returns the list of argument names for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.
get_iproc_body	Returns the body for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.
get_iproc_list	Returns the current fault model type, as previously specified by the set_fault_type command.
get_logical_library_list	Returns a Tcl list with all logical design library names defined with the set_logical_design_libraries command.
get_license_queue_timeout	Returns the amount of time Tessent Shell will queue for a required license as specified by the previous set_license_queue_timeout command, or its default value of “unlimited’ if the set_license_queue_timeout command was not issued or it was issued with that value.
get_modules	Returns a collection of all modules that match the specified name_patterns list.
get_multiprocessing_option	Returns the value of a single specified variable previously set with the set_multiprocessing_options command.
get_name_list	Returns the name(s) of the specified object(s).
get_nets	Returns a collection of all hierarchical nets instantiated relative to the current design that match the specified name_patterns list, subject to filtering imposed by the other optional options.
get_open_pattern_set	Returns the name of the currently open pattern set.
get_pattern_cycle_count	Reports the total number of cycles in the currently loaded WGL or STIL test pattern set.
get_pattern_set_data	Returns requested details of the internal representation of the specified pattern set.
get_pattern_set_list	Returns a Tcl list of all existing and closed pattern sets in the order of their creation.

Table 7-2. Command Summary (cont.)

Command	Description
get_pattern_set_option	Returns the value of the requested option for the specified pattern_set_name.
get_pins	Returns a collection of all hierarchical pins instantiated relative to the current design that match the specified name_patterns list and subject to filtering imposed by the other optional options.
get_ports	Returns a collection of all hierarchical ports on a given module that match the specified name_patterns list and subjected to filtering imposed by the other options.
get_procfile_name	Returns the absolute path to the scratch directory.
get_resource	Returns true when all resources in the specified resource_list are available.
get_scratch_directory	Returns the absolute path to the scratch directory.
get_simulation_context_list	Returns the available simulation contexts in a Tcl list.
get_simulation_value_list	Returns a Tcl list of the simulation values on the specified gate_pin objects.
get_single_name	Returns a string with the name of the element specified by the object_spec argument.
get_system_mode	Returns the system mode.
get_test_end_icall_list	Returns the iCalls added to the test_end procedure by the set_test_end_icall commands. Each iCall is a list containing the iProc and its arguments.
get_test_setup_icall_list	Returns the iCalls added to the test_setup procedure by the set_test_setup_icall commands. Each iCall is a list containing the iProc and its arguments.
get_tool_info	Returns information about the current tool and the current run as a Tcl result.
get_trace_flat_model_option	Introspects the default behavior of the trace_flat_model command.
get_transcript_style	Returns the keyword that specifies the style in which the tool transcripts commands.
get_tsdb_list	Returns a Tcl list of directory paths, relative to the current working directory, corresponding to all opened TSDB directories.

Table 7-2. Command Summary (cont.)

Command	Description
get_tsdb_output_directory	Returns the directory used by the process_dft_specification command which is the directory that has been previously set by the set_tsdb_output_directory command.
help	Lists commands and associated usage syntax.
history	Displays a list of previously executed commands.
iApply	Triggers the retargeting of all queued iRead and iWrite commands.
iCall	Calls an iProc registered against the ICL module associated with the specified effective_icl_instance_path.
iClock	Checks whether a controlling clock path from a valid clock source to the specified clock port exists.
iClockOverride	Models how the functional clocking has been programmed.
identify_redundant_faults	Identifies combinationally redundant (RE) faults from among those faults in the current fault list whose redundancy has not been determined yet.
iMerge	Specifies the beginning and the end of a set of iCall commands that are meant to be processed in parallel, as much as possible, in the final representation of the test patterns.
import_dfm	Imports a Calibre-compatible results database (RDB) file into a violations database (VDB).
index_collection	Extracts a single object at a specified index in a collection and creates a new collection containing only that object.
iNote	Inserts a note in the opened pattern set.
insert_test_logic	Inserts the test structures you define into the netlist to increase the design's testability.
intercept_connection	A command that uses the get_dft_cell command to obtain a cell with the specified function name and uses it to intercept a connection to a pin, port, or net.
iPrefix	Sets the iPrefix path that is used to compute the effective_icl_instance_path for the iCall command and other PDL commands.
iProc	Specifies a PDL procedure that can run later when referenced by the iCall command.

Table 7-2. Command Summary (cont.)

Command	Description
iProcsForModule	Specifies the ICL module for which subsequent iProc commands refer to.
iRead	Adds a read operation to the command queue that will be solved by the next iApply command.
iRelease	Releases the ownership of a resource that has been reserved by iTake.
iReset	Adds a sequence of actions to the current pattern set that is required to set the ICL network into the reset state.
iRunLoop	Creates a vector loop of a given duration.
is_collection	Indicates whether string is a collection handle.
iTake	Used inside of an iProc to reserve a resource (a port, a register or an instance) for exclusive use with this iProc.
iUseProcNameSpace	Specifies a name space that is used for all subsequent iCalls made within the iProc in which the iUseProcNameSpace command appears.
iWrite	Adds a write operation to the command queue that will be solved by the next iApply command.
launch_sid_tester	Directs Tessent Shell to launch the SID tester process on a local host using the selected_tester and the port number as specified in the configuration data file. Additionally, this command specifies an existing CDP or initializes a new CDP.
lock_current_registration	Locks all previously registered commands and attributes preventing them from being unregistered and modified.
macrotest	Runs the MacroTest utility to automatically generate manufacturing test patterns for embedded logic and memories referred to as macros. This utility is useful for applying specific patterns that test the insides of a macro, thereby improving overall IC test quality.
mark_display_instances	Changes the color of the specified instances in the schematic windows.
migrate_layout	Generates an LDB directory hierarchy that contains the specified preexisting LDB.
move_config_element	Moves a configuration element from one location to another.

Table 7-2. Command Summary (cont.)

Command	Description
move_connections	Turns off transcripting for the specified commands.
no_transcript	Turns off transcripting for the specified commands.
open_layout	Opens an existing Tessent Diagnosis tool-compatible Layout Database directory.
open_pattern_set	Opens an empty named pattern set and makes it ready to be populated with the specified PDL commands.
open_tsdb	Makes the content of TSDB directory visible to the tool. The specified TSDB output directory is automatically opened and does not need to be opened with this command.
open_visualizer	Opens the main DFTVisualizer window.
order_patterns	Reorders the internal test pattern set as specified.
printenv	Prints out the values of the Linux variables in the environment.
process_dft_specification	Validates and processes the content contained in a DftSpecification wrapper.
range_collection	Returns one or more adjacent elements from a collection and creates a new collection.
read_cell_library	Loads one or more cell libraries into the tool.
read_config_data	Reads the content of configuration data files or a string into the Tessent Shell environment.
read_core_descriptions	Reads the specified Tessent core description (TCD) files.
read_cpf	Loads a CPF (Common Power Format) file and removes any previously loaded power data. You can use multiple CPF files by using the native CPF “include” command.
read_failures	Checks the specified failure file for correct syntax and semantics and optionally appends a failure file.
read_fault_sites	Loads the path or bridge definitions or user-defined fault models (UDFM) contained in the specified ASCII file into the current tool session.
read_faults	Updates the current fault list with the faults contained in the specified fault file.
read_flat_model	Loads a flattened model into the tool.

Table 7-2. Command Summary (cont.)

Command	Description
read_icl	Reads ICL files into the internal ICL database.
read_modelfile	Initializes the specified RAM or ROM gate using the memory states contained in the named modelfile or deletes an earlier modelfile assignment.
read_patterns	Loads the external pattern set from the specified file.
read_procfile	Reads a test procedure file and merges the timing and named capture procedure data it contains with existing data loaded from previous test procedure files.
read_sdc	Reads false path and multicycle path information from a Synopsys Design Constraint (SDC) file.
read_sdf	Loads timing data from a Standard Delay Format (IEEE SDF P1497 Draft 0.10) file.
read_upf	Loads a UPF (Universal Power Format) file and removes any previously loaded power data.
read_verilog	Reads one or more Verilog files into the specified or default logical library.
read_vhdl	Loads one or more VHDL files.
read_visualizer_preferences	Reads a DFTVisualizer preferences file and sets current preferences as described in the file.
register_attribute	Registers a new user-defined attribute.
register_tcl_command	Registers a Tcl command and makes it available in the global name space.
remove_from_collection	Removes objects found in obj_spec from a collection, resulting in a new collection.
rename_instance	Renames the leaf name of an instance.
replace_instances	Replaces the module definition of an instance with a new module definition.
report_aborted_faults	Displays information on testable faults that remain undetected (UD) after the ATPG process.
report_atpg_constraints	Displays all the current ATPG state restrictions and the pins on which they reside.
report_atpg_functions	Displays all the current ATPG function definitions.

Table 7-2. Command Summary (cont.)

Command	Description
report_atpg_timing	Reports the current ATPG timing setup.
report_attributes	Creates a human readable report for the set of attributes based on the usage options.
report_bist_capture_ranges	Displays a list of the currently defined BIST capture ranges.
report_black_boxes	Displays information on blackboxes and undefined models.
report_bus_data	Displays the bus data information for either an individual bus gate or for the buses of a specific type.
report_bypass_chains	Displays the defined EDT bypass scan chain connections.
report_capture_handling	Displays any special data capture handling currently in use.
report_capture_procedures	Displays the cyclized information for a specified named capture procedure.
report_cell_constraints	Displays a list of the constrained cells.
report_cell_models	Displays a list of either all cell models or the DFT library models associated with the specified cell type.
report_chain_masks	Reports the list of masked scan chains and their associated unload value.
report_clock_controller_pins	Reports the clock controller pins specified with the set_clock_controller_pins command.
report_clock_controls	Displays current configuration information for clock control definitions.
report_clock_domains	Displays all clocks and their corresponding clock domain numbers.
report_clock_gating	Reports the clock gating instances that were identified as having unconnected ports and were connected to either the scan enable signal or to a user-specified signal or, reports the unconnected ports of the specified clock gating cells only.
report_clocks	Displays a list of all user-defined clocks and SDC-defined clocks.
report_compactor_connections	Displays defined scan chain connections for each EDT scan channel output.
report_context	Reports the current context as specified by the set_context command and any inferred subcontexts.

Table 7-2. Command Summary (cont.)

Command	Description
report_control_signals	Displays the rules checking results for control signals consisting of clocks added with the add_clocks command and pins identified for gating scannable memory elements with test logic.
report_core_instances	Reports the instance bindings created with the add_core_instances command, as well as the pattern count for patterns read in for each core.
report_design_sources	Reports the pathnames or file extensions previously specified with the set_design_sources command.
report_dfm_rules	Returns a tabular report of the DFM rules contained in the layout database.
report_dft_check	Generates scannability check information for all non-scan instances in the design, or within a specific hierarchical instance.
report_diagnosis	Writes the scan diagnosis report to standard I/O.
report_display_instances	Shows netlist information for the specified instances displayed in the Debug, Design, or Data window.
report_drc_rules	Displays either a summary of DRC violations (fails) or violation occurrence message(s).
report_edt_blocks	Displays a list of the current user-defined EDT block names (also referred to as block tags) and indicates which one, if any, represents the current block.
report_edt_configurations	Displays configuration information for the current compression logic.
report_edt_connections	Reports pin connections made during the top-level integration session.
report_edt_finder	Reports information about the EDT logic contained in a design.
report_edt_instances	Displays the instance pathnames of the top-level EDT logic, decompressor, and compactor.
report_edt_lockup_cells	Displays a tabular report of the lockup cells in the EDT logic.
report_edt_pins	Displays the currently defined names and inversion status of EDT channel and control pins.

Table 7-2. Command Summary (cont.)

Command	Description
report_environment	Displays the current value(s) of many of the most common “set_...” commands.
report_external_simulator	Displays the shell command the tool will use to invoke an external simulator for verifying patterns.
report_failures	Simulates the current design and test patterns and reports the failures in a pattern-based format.
report_false_paths	Displays false paths previously defined with the add_false_paths command.
report_fault_sites	Depending on the fault model, displays path definitions, bridge entries, or UDFM entries from the internal list.
report_faults	Displays fault information from the current fault list.
report_feedback_paths	Displays a report of currently identified feedback paths.
report_flattener_rules	Displays either a summary of all the flattening rule violations or the data for a specific violation.
report_gates	Displays the netlist information and simulation results for the specified gates and the simulation results for the specified user-defined ATPG functions.
report_icl_extraction_options	Provides a human readable report of the ICL extraction options.
report_icl_modules	Displays the netlist information and simulation results for the specified gates and the simulation results for the specified user-defined ATPG functions.
report_graybox_statistics	Reports the statistics gathered by graybox analysis.
report_id_stamp	Displays the unique identifier that the tool assigns each internal pattern set.
report_iddq_exceptions	Displays current exceptions to Iddq restrictions.
report_ijtag_instances	Reports options of instances for which there is a matched ICL module.
report_ijtag_logical_connections	Reports the logical paths that exist within the current design between the specified source and destination pins/ports, as well as all connections from or to the specified pins/ports. If no pin or port connections are specified, all logical connections are listed.

Table 7-2. Command Summary (cont.)

Command	Description
report_ijtag_retargeting_options	Reports the type and value of each option of the previous set_ijtag_retargeting_options command or their default values if the set_ijtag_retargeting_options command was not issued.
report_input_constraints	Displays the present constraint status of primary input pins.
report_layout_rules	Provides detailed reporting of layout rule violations.
report_lbist_configuration	Reports the global logicBIST controller configuration parameters.
report_lbist_pins	Reports the LogicBIST controller pins using the set_lbist_pins command.
report_lfsr_connections	Displays a list of all the connections between Linear Feedback Shift Registers (LFSRs) and primary pins.
report_lfsrs	Displays a list of definitions for all the current Linear Feedback Shift Registers (LFSRs).
report_licenses	Reports the license features currently checked out by the tool.
report_lists	Displays the list of pins whose values the tool will report during simulation.
report_loops	Displays information about circuit loops.
report_lpct_configuration	Reports the current low pin count test controller (LPCT) parameters to the standard display output.
report_lpct_pins	Reports the low pin count test (LPCT) controller pins and connection information to the standard display output.
report_measure_cycles	Displays data for the specified components/cycles/patterns from the test patterns loaded for the current session. If nothing is specified, data for all the test patterns is reported.
report_mismatch_sources	Displays the sources of simulation mismatches.
report_misrs	Reports the MISRs you have added to your design.
report_misr_connections	Reports MISR connections.
report_module_matching	Reports design modules and their matching ICL modules if the set_current_design command has been executed in ICL extraction mode prior.

Table 7-2. Command Summary (cont.)

Command	Description
report_module_matching_options	Reports the current settings defined by the set_module_matching_options command.
report_multicycle_paths	Displays multicycle path definitions you previously read into the tool using the read_sdc command.
report_multiprocessing_options	Displays the values of all variables used when executing multiprocessing commands for ATPG or fault simulation.
report_nofaults	Displays the nofault settings for the specified pin pathnames or pin names of instances.
report_nonscan_cells	Displays the non-scan cells whose model type you specify.
report_nonscan_models	Displays the sequential non-scan model list.
report_norace_clocks	Displays a list of all user-defined non-interacting clocks and their clock domain numbers.
report_notest_points	Displays all the circuit points for which you do not want the tool to insert controllability and observability.
report_output_masks	Displays a list of the currently masked primary output pins.
report_pattern_filtering	Displays the current pattern filtering configuration.
report_pattern_sets	Creates a report of a specified pattern set or of all pattern sets.
report_patterns	Displays information about patterns.
report_power_data	Reports the power data currently loaded in the system from either a read_cpf or read_upf command.
report_power_metrics	Displays shift and capture power metrics for specified test patterns.
report_primary_inputs	Displays a list of the primary inputs of a circuit.
report_primary_outputs	Displays the specified primary outputs.
report_procedures	Displays the specified procedure.
report_processors	Displays information about the processors used for the current multiprocessing environment.
report_read_controls	Displays all of the currently defined read control lines.
report_register_value	Reports register information for each register name.

Table 7-2. Command Summary (cont.)

Command	Description
report_resources	Displays the machine resources used by the active tool session.
report_scan_cells	Displays a report on the scan cells that reside in the specified scan chains.
report_scan_chains	Displays a report on all the current scan chains.
report_scan_enable	Reports on scan_enable signals and associated scan chains.
report_scan_groups	Displays a report on all the current scan chain groups.
report_scan_models	Displays the sequential scan models currently in the scan model list.
report_scan_partitions	Displays the scan partitions.
report_scan_pins	Displays all previously assigned scan input, output, and clock names.
report_scan_volume	Displays the volume of scan data used by the pattern set.
report_seq_transparent_procedures	Displays a list of seq_transparent test procedures along with the associated data that you specify.
report_sequential_fault_depth	Displays estimates of maximum test coverage possible with different sequential depth settings.
report_sequential_instances	Reports information and testability data for the sequential instances in the design.
report_shift_registers	Reports the identified shift registers in the design after switching to analysis mode.
report_simulation_contexts	Lists the available simulation contexts and indicates the current simulation context.
report_simulation_forces	Lists the active forces on the specified gate_pin objects.
report_statistics	Displays a detailed statistics report to the screen.
report_sub_chains	Displays a report on the scan subchains.
report_subchain_clocks	Reports on subchain clocks defined with the add_subchain_clocks command.
report_subchain_groups	Displays a report on the subchain groups.
report_test_logic	Displays the test logic that the tool added during the scan insertion process.

Table 7-2. Command Summary (cont.)

Command	Description
report_test_points	Displays both user-defined and system-defined test points.
report_test_stimulus	Displays the stimulus necessary to satisfy the specified set, write, or read conditions.
report_testability_data	Analyzes collapsed faults for the specified fault class and displays the analysis.
report_tied_signals	Displays a list of the tied floating signals and pins.
report_timeplate	Displays the specified timeplate.
report_udfm_statistics	Reports detailed fault coverage based on the UDFM defect models. The report contains columns for DS, DI, PT, TI, BL, RE, AU, UC, UO, UU, PU faults.
report_version_data	Displays the current software version information.
report_wrapper_cells	Reports information about the identified wrapper cells for each I/O port subjected to wrapper cell identification.
report_write_controls	Displays the currently defined write control lines and their off-states.
reset_attribute_value	Resets an attribute to its default value for the design objects specified in obj_spec.
reset_au_faults	Reclassifies the faults in certain untestable categories.
reset_bypass_chains	Removes user-specified EDT bypass chain connections.
reset_compactor_connections	Removes user-specified EDT compactor connections.
reset_design	Clears all design setup data but keeps the design and library in memory.
reset_di_faults	Reclassifies DI faults to the UC category.
reset_open_pattern_set	Clears the content of the currently open pattern set.
reset_state	Resets the circuit status.
restore_design	Discards all edits performed in insertion mode and restores the design to its state prior to entering insertion mode.
return_output	Accepts one or more tool command lines and returns the command output as a Tcl result.
select_display_instances	Selects the specified objects in the Debug and Design window(s).

Table 7-2. Command Summary (cont.)

Command	Description
set_abort_limit	Specifies the abort limit for the test pattern generator.
set_atpg_compression	Specifies for the ATPG to perform dynamic pattern compression.
set_atpg_fill	Specifies how the tool should fill unspecified bits in ATPG patterns.
set_atpg_limits	Specifies the ATPG process limits at which the tool terminates the ATPG process.
set_atpg_timing	Enables and defines parameters for timing-aware ATPG and fault simulation.
set_attribute_options	Modifies options of any registered user-defined attribute.
set_attribute_value	Sets an attribute's value for the objects specified in object_spec.
set_au_analysis	Specifies whether the ATPG uses the ATPG untestable information to place ATPG untestable faults directly in the AU fault class.
set_bidi_gating	Specifies how bidirectional (bidi) pins are controlled during scan chain shifting to prevent potential bus contention or to ensure an on/off state during testing.
set_bist_chain_test	Disables all capture clock activity for the specified number of patterns in the fault simulation during execution of the chain test.
set_bist_debug	Sets up a trace of LFSR(s) value during a pattern's shift cycles.
set_bist_debug	Sets up a trace of LFSR(s) value during a pattern's shift cycles.
set_bist_trace	Enables the tracing of PRPG and MISR values associated with each BIST pattern to facilitate signature mismatch debugging and other diagnostics.
set_bus_handling	Specifies the bus contention results that you desire for the identified buses.
set_bus_simulation	Specifies whether the tool uses global or local bus simulation analysis.
set_bypass_chains	Specifies a list of scan chains to connect in series to form a particular EDT bypass chain.

Table 7-2. Command Summary (cont.)

Command	Description
set_capture_clock	Specifies the capture clock for random pattern simulation or, optionally, for all ATPG pattern simulation.
set_capture_handling	Specifies how the tool globally handles the data capture of state elements that have C3 and C4 rule violations.
set_capture_procedures	Enables or disables the tool's use of a specified subset of named capture procedures when generating test patterns.
set_cell_library_options	Sets the specified options for library parsing and design elaboration.
set_cell_model_mapping	Overrides the non-scan to scan model mapping defined by the tool.
set_chain_test	Specifies binary sequences for chain test.
set_checkpointing_options	Enables checkpointing and specifies the associated options.
set_clock_controller_pins	Specifies the connection information for the clock controller pins.
set_clock_controls	Enables and disables the clock control definitions in the test procedure file.
set_clock_gating	Specifies clock gating cells whose unconnected scan enable ports need to be connected to either the scan enable signal or a specified signal (pin).
set_clock_gating_enable	Associates clocks that control clock gating devices with enable signal drivers.
set_clock_off_simulation	Enables or disables the simulation where all clock primary inputs are at their "off" value, other primary inputs have been forced to values, and state elements are at the values scanned in or resulting from capture in the previous cycle.
set_clock_restriction	Specifies whether ATPG can create patterns with more than one active capture clock.
set_compactor_connections	Specifies the scan chains for the tool to connect to a particular scan channel output.
set_contention_check	Specifies whether or not contention checking is on and the conditions under which checks are performed. Contention checking is set to On when the tool is invoked.
set_context	Specifies the current usage context of Tessent Shell.

Table 7-2. Command Summary (cont.)

Command	Description
set_current_design	Specifies the top level of the design for all subsequent commands until reset by another execution of this command.
set_current_edt_block	Directs the tool to apply certain subsequent commands to a particular EDT block only.
set_current_edt_configuration	Sets a particular compression configuration for the tool to use within the current design block.
set_current_mode	Specifies the current mode.
set_current_simulation_context	Sets the current simulation context.
set_decision_order	Specifies how the ATPG selects gate input or output nodes for evaluation during ATPG.
set_defaults_value	Sets a property inside one of the DefaultsSpecification/DftSpecification (policy) wrappers.
set_design_include_directories	Specifies one or more directory paths that contain `include files for use by subsequent read_verilog commands.
set_design_level	Specifies the current usage context of Tessent Shell.
set_design_macros	Specifies one or more defined macros for use by subsequent commands.
set_design_sources	Specifies where the tool should look for the definition of undefined modules in the list of files specified by the read_verilog and read_icl commands.
set_dft_enable_options	Enables or disables the control or observe points.
set_diagnosis_options	Specifies the type of diagnosis performed by the diagnose_failures command.
set_display	Sets the DISPLAY environment variable from the tool's command line.
set_dofile_abort	Specifies whether the tool aborts or continues dofile execution if it detects an error condition.
set_drc_handling	Specifies how the tool handles design rule violations.
set_driver_restriction	Specifies whether the tool allows multiple drivers on buses and multiple active ports on gates.
set_edt_finder	Enables the tool to automatically identify EDT logic and update scan chain pins during test pattern generation.

Table 7-2. Command Summary (cont.)

Command	Description
set_edt_instances	Specifies the location in which the tool places the EDT logic.
set_edt_mapping	Enables or disables automatic mapping of block-level dofile commands so block-level dofiles can be reused without modification for top-level pattern creation.
set_edt_options	Determines whether compression is on and specifies parameters for the EDT logic, including scan channels, bypass circuitry, lockup cells, pipeline stages, and compactor type.
set_edt_pins	By default, all EDT pins are created as dedicated pins with default names and no inversions. The same set_edt_pins command must be used for both the pattern generation phase and the EDT logic creation phase to generate patterns correctly for modified pins.
set_edt_power_controller	Generates and inserts a power controller in the compression logic to enable low-power shift.
set_external_capture_options	Specifies the number of tester cycles to be used in the capture window of all patterns.
set_external_simulator	Specifies the shell command to use to invoke an external simulator for verifying tool-produced patterns.
set_fails_report	Specifies whether the design rules checker displays clock rule failures.
set_fault_mode	Specifies whether the fault mode is collapsed or uncollapsed.
set_fault_protection	Specifies for the tool to protect detected faults from manipulation by subsequent tool commands.
set_fault_sampling	Specifies the fault sampling percentage used for circuit evaluation or scan identification.
set_fault_subclass_analysis	Turns on or off the analysis for the specified fault class(es).
set_fault_type	Specifies the fault model type for ATPG.
set_file_compression	Controls whether the tools read and write files with .Z or .gz extensions as compressed files (the default).
set_flattener_rule_handling	Specifies how the tool globally handles flattening violations.

Table 7-2. Command Summary (cont.)

Command	Description
set_gate_level	Specifies the hierarchical level of gate reporting and displaying.
set_gate_report	Specifies the information displayed by the report_gates command.
set_gzip_options	Specifies GNU gzip options to use with the GNU gzip command.
set_icl_extraction_options	Customizes the behavior of ICL extraction.
set_icl_scan_interface_ports	Sets the names of the ports in the specified scan interface previously added by add_icl_scan_interfaces that ICL extraction will create in the new ICL top module.
set_iddq_checks	Specifies the restrictions and conditions to use when creating or selecting patterns for detecting IDDQ faults.
set_iddq_strobe	Specifies on which patterns (cycles) the tool will simulate IDDQ measurements.
set_ijtag_instance_options	Sets options on instances for which there is a matched ICL module.
set_ijtag_retargeting_options	Enables you to configure different aspects of ijtag retargeting.
set_insertion_options	Specifies the values for the insertion options. The option settings affect the behavior of the insertion commands.
set_insert_test_logic_options	Specifies a prefix that overrides the default prefix “ts_” that is used when creating the test point logic.
set_internal_fault	Specifies whether the tool allows faults within or only on the boundary of library models.
set_internal_name	Specifies whether to delete or keep pin names of library internal pins containing no-fault attributes.
set_io_mask	Modifies the behavior of bidirectional pins so that their expected values will always be X during test cycles in which the primary input portion of the bidirectional pin is being forced.
set_latch_handling	Specifies whether the tool considers non-transparent latches for scan insertion while test logic is turned on.
set_lbist_controller_options	Specifies global options to configure the logicBIST controller.

Table 7-2. Command Summary (cont.)

Command	Description
set_lbist_instances	Specifies the instance in which the logicBIST controller or single chain mode logic is placed.
set_lbist_pins	Specifies the connection information for logicBIST controller pins.
set_lbist_power_controller_options	Specifies creation of the low-power shift controller for LogicBIST.
set_learn_report	Specifies whether the report_gates command can display the learned behavior for a specific gate.
set_lfsr_seed	Sets the initial value of a PRPG or a MISR.
set_lfsrs	Changes the shift_type and tap_type default setting for the add_lfsrs and add_lfsr_taps commands.
set_license_queue_timeout	Specifies the amount of time Tessent Shell will queue for a required license if it is not immediately available.
set_list_file	Specifies the name of the list file into which the tool places the pins' logic values during simulation.
set_lockup_cell	Enables the automatic insertion of lockup cells.
set_logfile_handling	Specifies for the tool to direct the transcript information to a file.
set_logical_design_libraries	Defines the set of available logical libraries that can be used by the read_verilog and read_vhdl -in_library option.
set_loop_handling	Specifies how the tool handles feedback networks.
set_lpct_condition_bits	Specifies the condition scan cells (condition bits) in the design core to connect to the Type 3 low pin count test (LPCT) controller.
set_lpct_controller	Enables the creation of and specifies the configurations for a low pin count test (LPCT) controller for use with EDT logic.
set_lpct_instances	Inserts the low pin count test (LPCT) controller and clock gater in a specified hierarchical instance within the design core.
set_lpct_pins	Specifies control pins and connections between the low pin count test (LPCT) controller and the core design.
set_macrotest_options	Prepares a black box macro to allow MacroTest conversion of patterns at the boundaries of that instance.

Table 7-2. Command Summary (cont.)

Command	Description
set_misr_connections	Describes the connections between the scan chain outputs and the MISR.
set_module_matching_options	Defines the acceptable prefixes and suffixes or regular expressions to use when matching an ICL module to a design module during ICL extraction.
set_multiple_detection	Enables the multiple detection of faults.
set_multiprocessing_options	Sets the values of several variables that affect multiprocessing commands for ATPG or simulation.
set_name_prefix	Explicitly defines the default names for nets and instances, and reports current or modified settings.
set_net_dominance	Specifies the fault effect of bus contention on tri-state nets.
set_net_resolution	Specifies the behavior of multi-driver nets.
set_number_shifts	Sets the number of shifts for loading or unloading the scan chains.
set_observation_point	Specifies the observation point for random pattern fault simulation.
set_output_masks	Ignores any fault effects that propagate to the primary output pins you select.
set_parallel_load_subchains	Specifies whether the internal parallel access functionality is enabled or disabled.
set_pathdelay_holdpi	Specifies whether the ATPG keeps non-clock primary inputs at a constant state after the first force.
set_pattern_buffer	Stores run-time pattern data in temporary files in the directory specified.
set_pattern_classification	Specifies the order in which to store test patterns.
set_pattern_filtering	Creates a temporary set of sampled scan patterns.
set_pattern_source	Specifies the source of the test patterns.
set_pattern_type	Specifies the type of pattern(s) used by ATPG simulation.
set_physical_translation	Translates special Verilog characters to SPICE-readable characters Calibre applications can read.
set_possible_credit	Specifies the percentage of credit that the tool assigns possible-detected faults.

Table 7-2. Command Summary (cont.)

Command	Description
set_power_control	Enables low-power ATPG and sets up a switching and/or capture threshold.
set_power_domain	Specifies the number or the length of scan chains to be generated for the given power domains.
set_power_metrics	Calculates shift and capture power during test pattern generation and simulation.
set_procedure_cycle_checking	Enables test procedure cycle timing checking to be done immediately following scan chain tracing during design rules checking.
set_procedure_retargeting_options	Controls the behavior of the automatic merging and mapping (retargeting) of core-level load_unload and shift procedures to top-level test procedures and mapping of core-level test_setup and test_end IJTAG procedures.
set_procfile_name	Specifies a new procedure file for the tool to process at a later time.
set_ram_initialization	Specifies whether to initialize RAM and ROM gates that do not have initialization files.
set_ram_test	Specifies the mode for RAM testing with random patterns.
set_random_atpg	Specifies whether the tool uses random patterns during ATPG.
set_random_clocks	Specifies whether Tessent FastScan uses combinational or clock_sequential patterns for random pattern simulation.
set_random_patterns	Specifies the number of random patterns that the tool simulates.
set_register_value	Provides a method for specifying the register value variable outside of Setup mode.
set_registered_io	Turns on the automatic registration of the primary I/O pins of the design.
set_relevant_coverage	Determines which sub-class(es) of untestable faults are included in or excluded from the relevant coverage reported by the tool.
set_scan_enable	Assigns scan_enable signals to specific scan chains.
set_scan_enable_sharing	Divides all scan chains into specified groups and assigns a unique scan_ enable signal to each group.

Table 7-2. Command Summary (cont.)

Command	Description
set_scan_insertion	Specifies the input control signals' drivers used by the insert_test_logic command.
set_scan_pins	Changes the scan-in or scan-out pin naming parameters to index or bus format.
set_screen_display	Specifies whether the tool writes the transcript to the session window.
set_shadow_check	Specifies whether the tool will identify sequential elements as a "shadow" element during scan chain tracing.
set_shift_register_identification	Enables/disables shift register identification. The default is ON.
set_simulation_options	Controls parallel simulation behavior.
set_skewed_load	Specifies whether Tessent FastScan includes a skewed load in the patterns.
set_split_capture_cycle	Controls whether the tool updates simulation data between clock edges.
set_stability_check	Specifies whether the tool checks the effect of applying the main shift procedure on non-scan cells.
set_static_learning	Specifies whether the tool performs the learning analysis to make the ATPG process more efficient.
set_system_mode	Specifies the operational state you want the tool to enter.
set_test_end_icall	Adds an iCall to the start of the test_end procedure.
set_test_logic	Inserts test logic to control the set, reset, clock, enable, or write control signals to make them scannable when scan chains are inserted.
set_test_point_analysis_options	Sets the maximum number of test points, the breakdown in control and observe points, the target fault coverage and the number of pseudo random patterns to be applied and some other parameters that are taken into account during test point analysis.
set_test_point_insertion_options	Sets the following test point insertion related parameters: - name of the test point enable signals. - number of test points that will be observed using a single flip-flop. - connect the clock port of all newly inserted flip-flops to a global test_clock signal instead of re-using existing clock signals.
set_test_setup_icall	Adds an iCall to the end of the test_setup procedure.

Table 7-2. Command Summary (cont.)

Command	Description
set_tied_signals	Changes the default value for floating pins and floating nets which do not have assigned values.
set_timing_exceptions_handling	Changes the default handling of timing exception paths (false paths and multicycle paths) read by the read_sdc command.
set_tla_loop_handling	Specifies how to simulate feedback loops that contain transparent latches (TLAs).
set_trace_report	Specifies whether the tool displays gates in the scan chain trace.
set_transcript_style	Specifies the style in which the tool transcripts commands.
set_transient_detection	Specifies whether the tool detects all zero width events on the clock lines of state elements.
set_transition_holdpi	Specifies for the tool to freeze all primary input values other than clocks and RAM controls during multiple cycles of pattern generation.
set_tristate_gating	Specifies how tri-state devices are controlled during scan chain shifting.
set_tsdb_output_directory	Sets the tsdb output directory used by the process_dft_specification command.
set_visualizer_logging	Writes the commands entered into the Transcript window to the file specified by the enhanced_dofile argument.
set_visualizer_preferences	Controls a subset of DFTVisualizer preferences for the Debug and Design windows.
set_wrapper_chains	Specifies wrapper chains for scan insertion.
set_xbounding_options	Sets up the parameters for X bounding insertion. The analysis is triggered by the analyze_xbounding command.
set_xclock_handling	Specifies whether the sequential element model outputs X when any of its clock inputs become X.
set_z_handling	Specifies the simulation handling for high impedance signals on internal and external tri-state nets.
set_zhold_behavior	Specifies whether ZHOLD gates retain their state values.
setenv	Sets a shell environment variable within the tool environment.

Table 7-2. Command Summary (cont.)

Command	Description
shutdown_sid_tester	Terminates the currently active SID tester process that was created by executing the launch_sid_tester command.
simulate_clock_pulses	Pulses one or more clocks within the current simulation context.
simulate_forces	Simulates the queued forces in the current simulation context.
simulate_patterns	Performs simulation by applying the specified pattern source.
sizeof_collection	Returns the number of objects in a collection.
sort_collection	Sorts a collection based on the value of one or more attributes, resulting in a new sorted collection.
system	Passes the specified command to the operating system for execution.
trace_flat_model	Traces the flat model taking into account the current simulation context.
uncompress_layout	Uncompresses a Layout Database.
uniquify_instances	Uniquifies the module definition of the specified instance objects found in obj_spec.
unmark_display_instances	Returns the specified marked instances to their original color. Color marking occurs with the mark_display_instances command.
unregister_attribute	Unregisters a user-defined attribute that was registered using the register_attribute command.
unregister_tcl_command	Unregisters the command called command_name that was previously registered using the register_tcl_command.
unselect_display_instances	Unselects the specified objects in the Debug and Design window(s).
unsetenv	Unsets a shell environment variable within the tool environment.
update_implication_detections	Performs an analysis on the undetected and possibly detected faults to determine if any of those faults can be classified as detected-by-implication.

Table 7-2. Command Summary (cont.)

Command	Description
verify_patterns	Performs pattern verification for diagnosis, and creates, updates, or loads the Diagnosis Startup Cache for use with the diagnosis tool.
write_atpg_setup	Writes a test procedure file and the dofile file for the existing scan chains.
write_core_description	Writes out the core description corresponding to the current chip level.
write_core_timing_constraints	Creates timing (SDC) files that provide the constraints related to the scan path and ATPG settings in the core design.
write_design	Writes the current design in Verilog netlist format to the specified file.
write_diagnosis	Writes diagnosis reports in text, comma separated values (CSV), and layout (physical) marker location formats.
write_edt_files	Creates the files that implement the EDT logic.
write_failing_paths	Reports, for each diagnosed symptom from a failure log, the scan pattern number, suspect(s) and paths.
write_failures	Injects faults and/or writes failing pattern results to a file.
write_fault_sites	Writes path definitions or bridge entries from the internal list to a file.
write_faults	Writes fault information from the current fault list to a file.
write_flat_model	Saves the flattened circuit model, the scan trace, and all DRC-related information to a specific binary file.
write_icl	Writes out ICL modules created and/or read in with the read_icl command to the specified file.
write_loops	Writes a list of all the current loops to a file.
write_modelfile	Writes all internal states for a RAM or ROM gate into the file that you specify.
write_patterns	Saves the current test pattern set to a file in a specified format.
write_primary_inputs	Writes primary inputs to the specified file.
write_primary_outputs	Writes primary outputs to the specified file.

Table 7-2. Command Summary (cont.)

Command	Description
write_procedure_testbench	Writes a test bench for verifying correct operation of internal signals used in procedures.
write_procfile	Writes existing procedure and timing data to the named test procedure file.
write_scan_order	Writes out the scan chains in the design using the DEF language.
write_scan_setup	Writes out a dofile containing all necessary steps for scan insertion.
write_subchain_setup	Writes the appropriate add_sub_chains commands to a file so that the tool can understand the pre-existing scan subchains at the top-level of this module.
write_test_point_dofile	Writes out a dofile containing the test points.
write_visualizer_dofile	Writes a dofile containing the commands needed to recreate the current instance and data sets displayed in the DFTVisualizer windows.
write_visualizer_preferences	Writes the current DFTVisualizer preference settings to the specified file.
write_window_contents	Saves the current content of the specified DFTVisualizer window to the specified file.

Command Descriptions

This section describes, in alphabetical order, each command available in Tessent Shell. The beginning of each command description shows the contexts and modes that support the command and provides the following information:

Context: Lists each context and sub-context that supports the command. "All contexts" means that the command is supported in all available contexts. "Unspecified" means that you do not have to set a context to use the command.

Mode: Lists each mode that supports the command. "All modes" means that the command is supported in all available modes. In some cases, a particular mode supports the command only within certain contexts, and this is noted in parentheses after the mode type.

add_ambiguous_paths

Context: dft -scan, dft -edt, dft -test_points, patterns -scan

Mode: analysis

Usage

add_ambiguous_paths {***path_name*** | **-All**} [-Max_paths *number*]

Description

Specifies to derive multiple paths from ambiguous paths when there is path or edge ambiguity.

When paths have path and/or edge ambiguity, by default Tessent FastScan and Tessent TestKompress select a single path that satisfies the pin connectivity within the path definition file. If you want the tool to have additional choices for path and/or edge ambiguity, you can use the add_ambiguous_paths command. When Tessent FastScan or Tessent TestKompress select from the ambiguous paths, they only consider the possible connectivity between points and do not attempt to determine whether the edges are sensitive. Moreover, the tool marks all derived paths as unambiguous paths.

For more information on path delay faults, see "Creating a Path Delay Test Set" in the *Tessent Tessent Scan and ATPG User's Manual*.

Arguments

- ***path_name***

  A string that specifies the name of an ambiguous path from which you want the tool to derive unambiguous paths and add them to the path list.

- **-All**

  A switch that adds up to -Max_paths unambiguous paths for each ambiguous path encountered in the path list.

- -Max_paths *number*

  An optional switch and integer pair that specifies the maximum number of unambiguous paths you want the tool to derive. If you issue the command without this switch, the default maximum number of unambiguous paths is 10.

Note

Mentor Graphics recommends you use this switch with a large enough number to ensure you get all the unambiguous paths derivable from any ambiguous path. You will know the specified number is large enough if a message similar to "// All unambiguous paths...were added to the path list" is displayed in the transcript. If the message begins with a number (for example, "// 10 paths... were added to the path list"), it indicates the tool did not get all the derivable unambiguous paths.

Example

The following example loads in a path definition file and changes the maximum number of paths to five:

```
read_fault_sites /user/design/pathfile
add_ambiguous_paths -all -max_paths 5
```

Related Commands

delete_fault_sites
read_fault_sites
write_patterns

add_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_atpg_constraints {**0** | **1** | **Z**} {***pin_pathname*** | ***gate_id#*** | {***function_name*** |
{**-Cell** ***cell_name*** {***pin_name***…}}}… [-Instance {*object_expression*…}]
[-MODUle {*module_name* …}]}… [-DYnamic | -STatic]
[-NOCapclock_check | -Load_only]

Description

Restricts all patterns placed into the internal pattern set according to the user-defined constraints.

When a simulated pattern is rejected, a message is issued that indicates the number of rejected patterns and the first gate at which the failure occurred. You can control the severity of the violation with the set_contention_check command. If you set the checking severity to Error, the simulation is terminated if it rejects a pattern due to a user-defined constraint. You can analyze the simulation data up to the termination point by using the report_gates command with the Error_pattern option.

User-defined constraints are used when using Tessent FastScan or Tessent TestKompress to generate test patterns with deterministic test generation methods. When test patterns are generated randomly using Tessent FastScan or Tessent TestKompress, the use of the user-defined ATPG constraints is not ensured; however; non-conforming random patterns are rejected.

If you change an ATPG constraint for a single internal set of patterns, pattern compression continues using the new constraints, which can cause the good patterns to be rejected; therefore, you should remove all ATPG constraints before compressing the pattern set.

Note

If you constrain a pin by directly creating an ATPG constraint to the *pin_pathname*, and then create another constraint that indirectly creates a different constraint, the constraint that directly specified the *pin_pathname* (overriding the global ATPG cell constraint) is used.

The -Dynamic switch lets you change the ATPG constraints any time during the ATPG process, affecting only the fault simulation and capture that occurs after the constraint changes. Any subsequently simulated patterns that fail to meet the current constraints are rejected during fault simulation.

Dynamic ATPG constraints do not affect DRC because of their temporary nature. Static ATPG constraints are unchangeable in analysis mode, ensuring that DRC must be repeated if they are changed.

Arguments

- **0 | 1 | Z**

  A literal that restricts the named object to a low state, high state, or high impedance state, respectively. You must choose one of the three literals to indicate the state value to which you want the tool to constrain the specified object.

The following lists the four objects on which you can place the constraint. You can use any number of the four argument choices in any order.

- ***pin_pathname***

  A repeatable string specifying the pathname of a top-level pin or a library model pin on which you are placing the constraint. Pathnames of pins on intermediate hierarchy modules are not supported.

- ***gate_id#***

  A repeatable integer specifying the gate identification number of the gate you want to constrain.

- ***function_name***

  A repeatable string specifying the name of a function you created with the add_atpg_functions command. If you place a constraint on an ATPG function that you generated with the add_atpg_functions -Cell command, all cells affected by that ATPG function are also constrained. You can delete all these constraints using the *function_name* argument with the delete_atpg_constraints command.

- **-Cell *cell_name*** {***pin_name***}

  A repeatable switch and string pair specifying the name of a DFT library cell and name of a pin on that cell. You can repeat the *pin_name* argument if there are multiple pins or nets on a cell that you need to constrain. If you use the -Cell option, an ATPG constraint is placed on every occurrence of that cell within the design.

- -Instance *object_expression*

  An optional switch and repeatable string pair that places ATPG constraints inside the specified list of instances. You can use regular expressions, which may include any number of embedded asterisk (*) and/or question mark (?) wildcard characters. You can only use this switch when using the -Cell switch or when a function name is specified.

- -MODUle *module_name*

  An optional switch and repeatable string pair that places the ATPG constraints inside all instances of the specified module.

- -DYnamic

  An optional switch that satisfies only the ATPG constraints during the ATPG process and not during DRC. You can change these constraints during the ATPG process; therefore, DRC does not check these constraints. This is the default.

- -STatic

  An optional switch that satisfies the ATPG constraints you are defining during all its processes. You can only add or delete static ATPG constraints when you are in Setup mode, ensuring the static ATPG constraints are used for all ATPG analyses during design rules checking. DRC checks for any violations of ATPG constraints during the simulation of the test procedures (rule E12).

- -NOCapclock_check

  An optional switch that suppresses checking of specified ATPG constraints after the capture clock. By default, ATPG constraints are checked at the same time as bus contention. If contention checking is performed after the capture clock, ATPG constraints are also checked after the capture clock. You cannot use this switch and -Load_only at the same time.

  In some situations, you may have some ATPG constraints that do not need to be checked after the capture clock; although, you may want other constraints and bus contention to be checked after the capture clock. In this case, you can use the -Nocapclock_check switch on certain constraints to suppress checking of those constraints after the capture clock.

- -Load_only

  An optional switch specifying the Atpg constraint only applies to the first cycle after shift. When using Tessent FastScan or Tessent TestKompress, the values loaded into the scan chain and the forced PI values satisfy the constraint; however, once the leading edge of the first clock occurs, the constraint no longer applies (as if it were temporarily deleted until the next load, then re-added). Constraints added using the -Load_only option are satisfied by each scan load of a RAM sequential pattern and by each scan load of a clock sequential multiple load pattern. A clock sequential multiple load pattern occurs when you issue the set_pattern_type command with the -Multiple_load switch on, and the -Sequential switch set to 2 or more. Note that you cannot use the -Load_only and -NOCapclock_check switches at the same time.

Example 1

The following example creates a user-defined ATPG function and then uses it when creating ATPG pin constraints:

```
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
```

Example 2

The following example creates a user-defined ATPG function and then uses it when creating ATPG constraints. The ATPG constraints are added to the instances inside core1 only.

```
add_atpg_functions mux_1hotse1 SELECT1 -cell imux3sux2 S2 S1 S0
add_atpg_constraints 1 mux_1hotsel -instance core1
```

Example 3

The following example adds ATPG constraints to all occurrences of the specified cell inside the instances with pathnames that begin with “/core1/u19/reg”.

```
add_atpg_constraints 1 -cell imux3sux2 S1 -instance /core1/u19/reg*
```

Example 4

The following example shows how to use wildcards in the second level of hierarchy.

```
add_atpg_constraints 1 -cell imux3sux2 S1 -instance /core1/*/reg*
```

Related Commands

add_atpg_functions

add_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_atpg_functions ***function_name type*** {***pin_pathname*** | ***gate_id#*** | ***existing_function_name*** | {**-Cell** ***cell_name*** {***pin_name*** | **-Function** ***type pin_name***...}...}}...

Description

Creates an ATPG function that you can then use when generating user-defined ATPG constraints.

You can specify any combination of pin pathnames, gate identification numbers, and previously user-defined functions. You can precede any object with the tilde (~) character to indicate an inverted input with respect to the function. If you specify an input pin pathname, the tool automatically converts it to the output pin of the gate that drives that input pin.

Arguments

- ***function_name***

  A required string that specifies the name of the ATPG function you are creating. You can use this *function_name* as an argument to the add_atpg_constraints command.

- ***type***

  A required argument specifying the operation that the function performs on the selected objects. The choices for the *type* argument, from which you can select only one, are as follows:

  And — The output of the function is the same as for a standard AND gate.

  Or — The output of the function is the same as for a standard OR gate.

  Equiv — The output of the function is a high state (1) if all its inputs are at a low state (0), or if all its inputs are at a high state (1). So, the function's output is a low state if there is at least one input at a low state and at least one input at a high state.

  Select — The output of the function is a high state (1) if all its inputs are at a low state (0) or if one input is at a high state and the other inputs are at a low state. So, if there are at least two inputs at a high state, the function's output is at a low state.

  SELECT1 — The output of the function is a high state (1) if one input is at a high state and the other inputs are at a low state (0). So, the function's output is a low state if there are at least two inputs at a high state or all inputs are at a low state.

The following lists the objects on which the function operates. You can use any number of the argument choices in any order.

- ***pin_pathname***

  A repeatable string that specifies the pathname to the pin on which you are placing the function. If you specify an input pin name, it is automatically replaced with the output pin of the gate that drives that input pin.

- ***gate_ID#***

  A repeatable integer that specifies the gate identification number.

- ***existing_function_name***

  A repeatable string that specifies the name of another function you created with the add_atpg_functions command. The *existing_function_name* argument cannot be the same as any pin name in the design. This string cannot be used with the -Cell option.

- **-Cell *cell_name*** {***pin_name*** | **-Function *type pin_name***}

  A repeatable switch with a corresponding pair of strings that specify the name of a DFT library cell or pin on that cell. You can repeat the *pin_name* argument if you need to constrain multiple pins or nets on a cell.

  The -Function switch is a repeatable switch with corresponding strings that specify the function type and a list of specific pins on cell *cell_name* that are arguments to the function. You can repeat the *pin_name* argument if you need to constrain multiple pins. This switch allows you to define a maximum of two layers of functions with the -Cell switch. Normally, you can define two functions, f1 and f2, and then add a third function, f3, that refers to f1 and f2. However, this is not allowed when you use the -Cell switch.

  For information on how this switch is used, see Example 2.

  If you use the -Cell option, an ATPG function is placed on every occurrence of that cell within the design.

Example 1

The following example creates an ATPG function and then uses it in an add_atpg_constraints command:

```
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 1 and_b_in
```

Example 2

The following example generates multiple levels of ATPG functions when using the -Cell switch.

For every instantiation of the OR4 cell, the following function is implemented:

```
[ ( A AND B ) OR ( C OR D ) ]
```

where A, B, C, and D are inputs of the OR4 cell. Normally, you can define two functions, f1 and f2, then add a third function, f3, that refers to f1 and f2. However, when you use the -Cell switch with the add_atpg_functions command, this is not possible. You can use the -Function switch to define up to two levels of functions using the -Cell switch. The syntax is as follows:

```
add_atpg_functions top_function or -cell OR4 -function and A B
                   -function or C D
```

This implemented the previously mentioned function, which can be confirmed with the report_atpg_functions command.

Example 3

The following example assigns the two Q outputs of scan cells /u11 and /u12 to always have the same assigned state after loading.

```
add_atpg_functions CELL_INCLUSIVE equiv /u11/Q /u12/Q
add_atpg_constraints 1 CELL_INCLUSIVE
```

Example 4

The following example causes one input to always be the opposite from the other. The tilde (~) character is the negation symbol.

```
add_atpg_functions CELL_EXCLUSIVE equiv ~ /u71/Q /u72/Q
add_atpg_constraints 1 CELL_EXCLUSIVE
```

add_bist_capture_range

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_bist_capture_range ***atpg_capture_proc_name*** [***start_value stop_value***]

Description

Associates a named ATPG capture procedure with a subset of the BIST patterns.

Hybrid TK/LBIST Flow Usage

The add_bist_capture_range command is added once per NCP. Once all the NCPs are applied, the tool restarts from the first NCP.

Additionally, the command is automatically added to the LogicBIST fault simulation dofile written out during IP generation. For usage information, refer to "LogicBIST Fault Simulation and Pattern Creation" in the *Hybrid TK/LBIST Flow User's Manual*.

Arguments

- ***atpg_capture_proc_name***

  A required string that specifies the name of the ATPG capture procedure.

- ***start_value***

  A required argument that specifies the beginning of a contiguous range for a group of capture procedures. The tool typically generates the start and stop values in the BIST controller synthesis phase, and you should not change the values.

- ***stop_value***

  A required argument that specifies the end of a contiguous range for a group of capture procedures. The tool typically generates the start and stop values in the BIST controller synthesis phase, and you should not change the values.

Example

This example shows the association of NCPs with capture ranges corresponding to the specification - clk1_twice 34%, clk2_twice 33% and clk3_twice 33%:

```
add_bist_capture_range clk1_twice 0 87
add_bist_capture_range clk2_twice 88 171
add_bist_capture_range clk3_twice 172 255
```

set_lbist_controller_options

add_black_boxes

Context: all contexts

Mode: setup

Usage

add_black_boxes {{{-**Instances** ***ins_pathnames*** | -**Modules** ***module_names***}
[0 | 1 | X | Z]} [-Pin *pinname* {0 | 1 | X | Z}]…} | {-**Auto** [0 | 1 | X | Z]}
[-FAUlt_boundary | -NOFAUlt_boundary | -NO_Boundary]

Description

Defines instances of Verilog modules or ATPG library models as black boxes for ATPG and sets the constrained value on output or bidirectional black box pins.

You can blackbox a single instance, or every instance of a particular module or ATPG model that you do not want included in the next ATPG run. You can also use this command to automatically blackbox instances of nonexistent modules or ATPG library models.

When reading in a Verilog netlist, a warning message is issued when an instance is found that references a model (Verilog module or ATPG library model) that is not in the netlist or ATPG library. A referenced model for which a module or ATPG library model of the same name is not found in the netlist or ATPG library is considered to be undefined. You must blackbox instances of undefined models; otherwise, an error message is issued when you attempt to leave Setup mode or enter a create_flat_model command. The warning lists the names of referenced models that were not found in the netlist or ATPG library. You can also list the names using “report_black_boxes -undefined”.

Use add_black_boxes with the -Auto switch to automatically blackbox all instances of models that are considered to be undefined. By default, instances that are automatically blackboxed drive Xs on their outputs. Faults that propagate to the black box inputs are classified as ATPG_untestable (AU). You can use the add_black_boxes command to change the output values.

Issuing multiple add_black_boxes commands in succession, the first with the -Module switch and subsequent ones with -Instance, will globally blackbox all instances of a particular module or ATPG model while selectively blackboxing particular instances of the same module or ATPG model with slightly different pin values.

Tip: For optimal performance, issue all add_black_boxes commands before issuing any other commands.

Arguments

- -**Instances** ***ins_pathnames***

  A switch and string pair that specifies to blackbox the objects specified by the ins_pathnames argument. The ins_pathnames argument can be an instance, a Tcl list of instances, or a collection of instances.

Note

Blackboxing implemented using the -Instances switch always overrides blackboxing implemented with the -Modules switch.

- **-Modules *module_names***

  A switch and string pair that specifies to blackbox every instance of the Verilog module or ATPG library model specified by the module_names argument. The module_names argument can be an instance, a Tcl list of instances, or a collection of instances.

- **-Auto**

  A switch that blackboxes any netlist instance that references a model (Verilog module or ATPG library model) that is not in the netlist or in the ATPG library.

Note

To properly blackbox instances for Tessent FastScan MacroTest, use the -Instance or -Module switch. The -Auto switch is not intended for use with Tessent FastScan MacroTest. To ensure success, you must also define at least the module (or entity or ATPG library model) pins, including names, directions, and width of vectors.

- 0 | 1 | X | Z

  An optional literal that specifies pin tie values. When used with the -Instance or -Module switch, it specifies the tie value for any pin not explicitly defined by the -Pin switch. When used with -Auto, it specifies the tie value for every pin. If you specify no value for this option, then the set_tied_signals command's value is the default.

- -Pin *pinname* 0 | 1 | X | Z

  An optional, repeatable switch, string, and literal that specifies the tie value of a particular pin. Use this switch to explicitly define the tie value for a pin, overriding for that pin the global tie value in effect for the -Instance or -Module switch.

- -FAUlt_boundary

  A switch that keeps pin pathnames at the boundaries of all blackboxed instances and allows boundary pins to become fault sites. This is the default for `celldefine modules and library models.

- -NOFAUlt_boundary

  A switch that keeps pin pathnames at the boundaries of all blackboxed instances, but does not allow boundary pins to become fault sites. This is the default for blackboxed instances that are not `celldefine modules or library models.

- -NO_Boundary

  A switch that does not keep pin pathnames at the boundaries of all blackboxed instances and does not allow boundary pins to become fault sites.

Note

Do not include this switch when you use the add_black_boxes command to blackbox a macro for Tessent FastScan MacroTest. The Tessent FastScan macrotest command must be able to find pin pathnames at the macro boundary.

Example 1

The following example creates a black box for a module named “core,” with each output driven by a tie0 logic gate. The example then overrides, for the single instance “/core1” of the module “core,” the output value of pin1, so it is driven by a tie1 logic gate instead of a tie0. All other instances of the “core” module still have outputs driven by tie0 logic.

add_black_boxes -modules core 0
add_black_boxes -instances /core1 -pin pin1 1

Example 2

The following example shows the tool’s warning message for instances of undefined models. The example then creates black boxes for these instances.

```
//  Compiling library  ...
//  Reading Verilog Netlist ...
//  Reading Verilog file dfta_out/pipe_scan.v
//  Finished reading file dfta_out/pipe_scan.v
//  WARNING: Following modules are undefined:
//      ao21
//      and02
//  Use "add_black_boxes -auto" to treat these as black boxes.
```

add_black_boxes -auto

Example 3

The following example shows two commands that keep the pin pathnames at the boundary of each instance of the blackboxed module named “macro1.” Either command allows Tessent FastScan MacroTest to function properly:

add_black_boxes -modules macro1 -fault_boundary

add_black_boxes -modules macro1 -nofault_boundary

Example 4

The following example creates blackboxes for the collection of modules returned by the get_modules command. The get_modules command returns only those modules that have been marked by the user with the user-defined attribute mark_black_box.

add_black_boxes -modules [get_modules -filter mark_black_box]

Example 5

Similar to Example 4, this example operates on instances that have a user-defined attribute mark_black_box.

```
add_black_boxes -instances [get_instances -filter mark_black_box]
```

Example 6

The following example creates blackboxes by assigning the collection of modules returned by the get_modules command to a variable. The add_black_box command then operates on the collection contained in the to_black_box variable.

```
set to_black_box [get_modules -filter mark_black_box]
add_black_boxes -modules $to_black_box
```

add_browser_data

Context: all contexts

Mode: setup, analysis

Usage

add_browser_data {{**Gates** | **Primitives**} | {**Drc** [-All_fails | *rule_id*]} |
{**FAults** [-ALl | -Total | -Undet | *fault_class*]} | **T_coverage** | **F_coverage** | **Loss_TC** | **RELevant_test_coverage** | **ATpg_effectiveness}**
[-Tab Hierarchy | Library | Clocks]

Description

Adds the specified data to the active tab of the DFTVisualizer Browser window.

You can use the *-Tab* switch to specify to add the data column to a tab that is not active. You can specify multiple arguments in one execution of this command.

The add_browser_data command opens DFTVisualizer, if the tool is not already open, and then opens the Browser window. If the Hierarchy tab of the Browser window is active, the specified data displays for each hierarchical submodule instance listed in the Browser window. If data is not available, the column is blank for that instance.

Use the delete_browser_data command to delete data columns.

Arguments

- **Gates**

  Required literal that displays the number of Verilog primitives or ATPG library models in each instance listed in the Hierarchy tab of the Browser window.

- **Primitives**

  Required literal that displays the number of ATPG library primitives in each instance listed in the Hierarchy tab of the Browser window.

- **Drc**

  Required literal that displays DRC violations for instances listed in the Hierarchy tab of the Browser window. By default all DRC violations display. Options include:

  rule_id
  String that specifies a design rule to display statistics for. The *rule_id* must match the exact violation identification (ID) of the design rule. For a list of rule violation IDs, refer to "Design Rule Checking."

- **FAults (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the total number of detected faults for all instances listed in the Browser window. The total number of detected faults is the sum of all *uncollapsed* faults. This number/sum corresponds to the right-most column of data output by the report_statistics command. By default, all faults for each fault class display. Options include:

-Total
Switch that lists the number of total faults for all classes. This switch is valid in the Hierarchy and Clocks tabs of the Browser window.

-Undet
Switch that specifies to list the faults of the undetected (UD) class. This switch is valid in the Hierarchy tab of the Browser window.

fault_class
String that specifies a fault class to display faults for. This switch is valid in the Hierarchy and Clocks tabs of the Browser window. For a summary of available fault classes, refer to the report_faults command.

-ALl
Switch that specifies to display all faults classes. This option displays the following columns in the Browser window: UO, DS, DI, PT, UU, and AU. This switch is valid in the Hierarchy and Clocks tabs of the Browser window. This is the default.

- **F_coverage (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the fault coverage data for each instance. This switch is available in the Hierarchy, Library, and Clocks tabs of the Browser window.

- **T_coverage (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the test coverage data for each instance. This switch is available in the Hierarchy, Library, and Clocks tabs of the Browser window.

- **Loss_TC (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the undetected faults in an instance displayed as a percentage of the testable faults in the entire design. This switch is available in the Hierarchy, Library, and Clocks tabs of the Browser window.

- **RELevant_test_coverage (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the test coverage for each submodule after untestable faults have been added/deleted from test coverage calculations. This switch is available in the Hierarchy and Clocks tabs of the Browser window.

- **ATpg_effectiveness (Tessent FastScan, Tessent TestKompress, and Tessent Diagnosis only)**

  Required literal that displays the ATPG effectiveness data for each instance in the Browser window. This switch is available in the Hierarchy and Clocks tabs of the Browser window.

- -Tab Hierarchy | Library | Clocks

  Optional switch and literal that specify the tab in the Browser window to which the column is to be added. By default, the add_browser_data command adds data to the active window. You can use this switch to specify to add the data column to a tab that is not the active tab.

Examples

The following example adds a column displaying the number of primitives in each instance and as many additional columns as there are design rules that were violated during DRC, with each of the latter showing the number of violations of each particular rule. Because the -Tab argument is not specified, by default, the column is added to the active tab.

```
add_browser_data primitives drc
```

The next example clears the active tab of the data columns added in the previous example, and adds two columns that list the total number of C2 and C3 DRC violations:

```
delete_browser_data primitives drc
add_browser_data drc c2 drc c3
```

Related Commands

delete_browser_data

add_capture_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_capture_handling {**Old** | **New** | **X**} {***gate_id#*** | ***pin_pathname*** | ***instance_name*** | {**-Cell** ***cell_name***}}... [-SInk | -SOurce]

Description

> **Tip**: This command should rarely be used. For most designs, other than those that require mixed capture handling, you should not use this command but rather use split capture handling. Split capture handling is automatically set if needed when you use the create_patterns command. Alternatively, you can directly set split capture handling using the set_split_capture_cycle command.

Specifies the data capturing behavior for the given state element.

After changing the data capture handling for selected state elements with add_capture_handling, you need to issue the set_capture_handling command to allow the tool to automatically identify the upstream state elements with their associated sinks, and the downstream state elements with the associated sources you defined.

When you use the add_capture_handling command to change the data capture handling settings, you cannot define source points with the new handling behavior if they propagate to sink points that do not have the new behavior, or to non-clock primary outputs. If the tool has different capture handling behaviors for the same state element, the behavior you define with the add_capture_handling command overrides the behavior you globally defined with the set_capture_handling command.

Tessent FastScan and Tessent TestKompress limit the scope of the effect of the capture handling behavior to the circuitry between the source and the sink points. You cannot simulate a newly captured effect past the sink point.

You can change the simulation behavior of RAM models with data hold capability using the add_capture_handling command. This is useful in cases when it is required to model a RAM which has data hold capability but does not introduce any latency.

Arguments

You must choose one of the following three literals to indicate the data capture handling behavior for the specified state elements:

- **Old**

  A literal specifying that the source state elements determine their output values for data capture by using the data that existed prior to the current clock cycle. The tool then passes

the data on to the source state element's sink state elements. This option is the default behavior upon invocation of Tessent FastScan and Tessent TestKompress.

- **New**

  A literal specifying that the source state elements determine their output values for data capture by using the data from the current clock cycle. The tool then passes the data on to the source state element's sink state elements.

- **X**

  A literal specifying that the source state elements use the output values from the current clock cycle for data capture unless the previous values are different from the current values. If the values differ, the source passes unknown (X) values onto the source state element's sink state elements.

The following lists the methods for naming the state elements on which the function operates. You can use any number of the four argument choices, in any order.

- ***gate_id#***

  A repeatable integer that specifies the gate identification number of the object. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

- ***pin_pathname***

  A repeatable string that specifies the name of a pin within the design. When specifying a pin, the pin must either be an output pin or must connect directly to an internal DFF or memory element.

- ***instance_name***

  A repeatable string that specifies the name of a RAM instance within the design.

Note

The instance name parameter is only valid for RAM's and FF's.

- **-Cell *cell_name***

  A repeatable switch and string pair that specifies the name of a cell.

- -SInk

  An optional switch specifying that the state element you name is a termination point for data capture. This is the default.

- -SOurce

  An optional switch specifying that the state element you name is an origination point for data capture.

Example

The following example changes the data capture handling of a specific gate and then globally assigns the data capture handling for all C3 and C4 rules:

add_capture_handling new 1158 -source
set_capture_handling -te new

```
// Begin capture handling analysis: LS=OLD, TE=NEW (#C3=1
                      #C4=1), #user_pts=1/0
// Capture handling analysis completed: #sources=1,
                      #int_gates=3, #sinks=1, CPU_time=0.03 sec
// Warning: 1 scan source points with incompatible handling
                      were identified
```

Related Commands

delete_capture_handling
report_capture_handling
set_capture_handling

add_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

add_cdp_test ***test_name*** **-pattern** ***pattern_file***

Description

Creates a new test in the CDP. The test is based on the specified pattern file.

The newly created test allows the user to perform two test operations:

- Execute the pattern file to determine the pass/fail status.
- Execute the pattern file and collect failing data.

Arguments

- ***test_name***

  A required string that specifies the name of the test.

- **-pattern** ***pattern_file***

  A required switch and string pair that specifies the directory path for a standalone SVF test pattern file that will be associated with the test.

Example

The following example adds a test pattern file named “pat.svf” to the CDP and creates a test named “test1” for the pat.svf pattern file.

```
add_cdp_test test1 -pattern ./patterns/pat1.svf
```

Refer to “Executing an IJTAG Test Pattern” in *Tessent SiliconInsight User’s Manual for Tessent Shell* for a sample usage scenario.

delete_cdp_test

execute_cdp_test

add_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_cell_constraints {**-Drc C6**} |
{{{***chain_name cell_position***} | ***pin_pathname*** | {**-CHain** ***chain_name***} |
{**-CLock** ***clock_name*** [-Type {Latch | Flop}] } -Instances *instance_name* ...}
{**C0** | **C1** | **CX** | **OX** | **XX** | **TX** | **DX** | **SX** | **C0DX** | **C1DX**}
[-All_patterns | -Scan_patterns]}

Description

Constrains scan cells (also non-scan cells for CX, TX, DX, and SX constraints) to a constant value.

The add_cell_constraints command constrains scan cells slightly differently, depending on the tool. For the “patterns -scan” context, the command constrains a scan cell to a constant value during the ATPG process.

For all tools, you can identify a particular scan cell either by specifying a scan chain name along with the cell’s position in the scan chain, or by specifying an output pin pathname that connects to a scan memory element. The constraint value that you specify is placed at either the output pin or the scan cell MASTER. The “patterns -scan” context additionally provides the -Chain and -Clock switches for identifying groups of scan cells to receive a particular constraint.

The rules checker audits the correctness of the data that defines the constrained scan cells immediately after scan cell identification. The checker identifies all invalid scan cell constraints and an error condition occurs.

In the case of scan cells with improper controllability or observability, rather than rejecting these circuits, you can constrain (or mask) their controllability or observability.

Note

Adding constraints can lower test coverage.

Table 7-3 on page 406 shows how cell constraints affect the cell during load-capture-unload. The table shows the unloaded (expected) value of the cell given three possible scenarios during capture:

- Cell Not Disturbed: All of the cell's clock/set/reset ports are off.
- Cell Disturbed (same value captured): At least one of the cell's clock/set/reset ports are not off (either on or X), and the new stable capture value is the same as the old value in the cell. Because the tools perform a timeless simulation, the cell's new capture value may not be predictable for this scenario (for example, if a timing exception path drives this cell).

- Cell Disturbed (different value captured): At least one of the cell's clock/set/reset ports is not off (either on or X), and the new stable capture value is different from the old value in the cell.

Note that the table uses ‘a’ and ‘b’ to represent different Boolean values (for example, if a=1, then b=0 or X). Each constraint is described in more detail in the “Arguments” on page 407.

Table 7-3. Example Cell Value Changes with Different Constraints for Scan Patterns

Cycle:	Load	Last Capture			Unload
Constraint	**Loaded Value (initialized value)**	**Cell Not Disturbed**	**Cell Disturbed (same value captured)**	**Cell Disturbed (diff. value captured)**	**Unloaded Value**
No constraint	a	a	a	b	same as capture value
C0	0	0	0	b	same as capture value
C1	1	1	1	b	same as capture value
CX	X	X	X	b	same as capture value
OX	a	a	a	b	X
XX	X	X	a	b	X
TX	X	X	X	X	X
DX	a	a	X	X	same as capture value
SX	a	a	a	X	same as capture value
C0DX	0	0	X	X	same as capture value
C1DX	1	1	X	X	same as capture value

Table 7-4 shows, for chain patterns, the different load and unload values of a scan cell with different constraints applied. Notice for chain patterns that CX, XX and TX are equivalent, and DX and SX are the same as no constraint.

Table 7-4. Example Scan Cell Value Changes with Different Constraints for Chain Patterns

Constraint	Loaded Value	Unloaded Value
No constraint	a	a
C0	0	0
C1	1	1
CX	X	X
OX	a	X
XX	X	X
TX	X	X
DX	a	a
SX	a	a
C0DX	0	0
C1DX	1	1

Arguments

- **-Drc C6 (“patterns -scan” context only)**

  A switch and literal pair that specifies to add a DX cell constraint to each latch and flip-flop that results in a C6 violation during DRC. Because this switch could have a big impact on the test coverage, we strongly recommend that you use the “set_simulation_options -C6_mask_races on” command to resolve C6 violations that occur when either the data port is faster than the clock port, or when both ports have almost the same delay and it is indeterminate as to which port is faster. For more description of these issues, see the -C6_mask_races argument description for the set_simulation_options command.

- ***pin_pathname***

  A string that specifies the name of one of the following types of pins:

  - An output pin of the scan cell.
  - An output pin directly connected through only buffers and inverters to the output of a scan memory element. The scan memory element is set to the value that you specify such that the pin is at the constrained value.
  - An output pin of a non-scan cell if you are applying a CX, TX, DX, or SX constraint.

Except as noted above, the pin pathname must resolve to a scan memory element. Buffers and inverters may reside between the pin and the memory element.

You can also use an introspection command to generate a Tcl collection of pins. For example:

add_cell_constraints [get_gate_pins GO_ID_REG_reg_*/q -hierarchical] OX

- ***chain_name cell_position***

  A string pair that specifies the name of the scan chain and the position of the cell in the scan chain. The scan chain must be a currently-defined scan chain and the position must be an integer where 0 is the scan cell closest to the scan-out pin. You can determine the position of a cell within a scan chain by using the report_scan_cells command.

  The MASTER memory element of the specified scan cell is set to the value that you specify; there is no inversion. However, the tool may invert the output pin of the scan cell if there is anything between it and the MASTER memory element if inversion exists between the MASTER and the scan output pin of the scan cell only.

- **-CHain *chain_name* ("patterns -scan" context only)**

  A switch and string pair that places cell constraints on all cells in the specified scan chain, except any that are already constrained; this switch does not override a pre-existing cell constraint on a cell. This switch is valid in non-Setup system modes only.

- **-CLock *clock_name* ("patterns -scan" context only)**

  A switch and string pair that adds cell constraints to all latches and flip-flops controlled by the clock, *clock_name*. If the cell that includes the latch or flip-flop is already constrained, this switch does not override the pre-existing constraint. This switch is valid in non-Setup system modes only.

Note

This switch only supports constraint types OX, DX and SX.

- -Type Latch | Flop **("patterns -scan" context only)**

  An optional switch and literal pair that limits the -Clock switch's action to adding cell constraints on just the latches or just the flip-flops controlled by the clock, *clock_name*. This switch is valid in non-Setup system modes only.

- -Instances *instance_name* ...

  An optional switch and string pair that specifies one or more instance names upon which to add cell constraints. This switch supports all types of constraints for scan cells inside the specified instance.

  This switch also supports all types of constraints for non-scan cells and transparent latches in the scan path inside the specified instance, except for the following cases:

  - If the state element is learned as TIE-0 or TIE-1, you cannot add any cell constraint.

- If the DRC learns the state element with loading value 0 or 1 when switching to capture, you cannot add cell constraints C1 and C1DX to the state element with loading value 0, or add constraints C0 and C0DX to the state element with loading value 1.
- If the DRC analysis classifies the state element as TIE-X during capture, you cannot add C0, C1, C0DX, and C1DX cell constraints to this state element.
- If the DRC analysis classifies the state element as a transparent latch during capture, you cannot add C0, C1, C0DX, or C1DX cell constraints to this state element.
- You cannot add OX cell constraints to non-scan cells or transparent latches in the scan path.

- **C0**

  A literal that constrains the scan cell to load value 0 only.

- **C1**

  A literal that constrains the scan cell to load value 1 only.

- **CX**

  A literal that specifies to simulate the loaded scan cell or non-scan value as unknown (uncontrollable).

- **OX**

  A literal that specifies to simulate the unloaded scan cell value as unknown (unobservable).

- **XX**

  A literal that constrains the scan cell to be both uncontrollable and unobservable.

- **TX (“patterns -scan” context only)**

  A literal that constrains the scan cell or non-scan cell to TIE-X during test generation and simulation. Additionally, the logic value X will be loaded into and unloaded from the scan cell.

- **DX (“patterns -scan” context only)**

  A literal that specifies for the loaded value to remain until the cell (scan or non-scan) is disturbed by any on clock. When the cell is disturbed, the output value of the cell becomes X for subsequent cycles until the next scan load initializes it to a new value. The cell unloads an X if disturbed, but if not disturbed unloads the loaded value. The tool does not use a scan cell constrained to DX as an observation point.

  If you use “add_cell_constraints -drc c6”, the tool applies a DX constraint automatically to each latch and flip-flop that results in a C6 violation during DRC. See the description of the “-Drc C6” argument for more information.

- **SX ("patterns -scan" context only)**

  Similar to DX except that when the cell is disturbed by any on clock, the output value of the cell becomes X *only if the captured value is different* from the loaded (or initialization) value. The tool does not use a scan cell constrained to SX as an observation point.

Note

If "set_drc_handling d8 warning" is in effect for DRC, the tool will automatically apply an SX cell constraint to each D8 failing master cell. This will prevent D8-related simulation mismatches when you verify the patterns in a timing based simulator, but may reduce coverage. If you use "set_drc_handling d8 note" for DRC, the tool does not apply SX cell constraints for D8 violations, which ensures test coverage is not affected. But you should use note handling only for cell architectures you know will not produce mismatches.

- **C0DX ("patterns -scan" context only)**

  A literal that constrains the scan cell to both load value 0 only and to keep the loaded value until the cell is disturbed by any on clock (C0 and DX). After the clock disturbance, the unload data is X (masked).

- **C1DX ("patterns -scan" context only)**

  A literal that constrains the scan cell to both load value 1 only and to keep the loaded value until the cell is disturbed by any on clock (C1 and DX). After the clock disturbance, the unload data is X (masked).

- -Scan_patterns **("patterns -scan" context only)**

  An optional switch that applies the cell constraint only when creating scan test patterns.

- -All_patterns **("patterns -scan" context only)**

  An optional switch that applies the cell constraint when creating all patterns (scan and chain test patterns). Note that this switch is not valid with the -Drc switch in the same command line. This is the default.

Note

"dft -edt" context only: if you specify many binary constraints, the tool may not be able to create chain test patterns that satisfy all the constraints.

Example 1

The following example applies one constraint for use during the generation of scan patterns and one constraint for use during the generation of all patterns. Then it displays a list of all the constrained scan cells:

```
add_cell_constraints chain1 5 c0
add_cell_constraints /reg_d2_/Q ox -all_patterns
report_cell_constraints
```

```
// constraint chain   cell   cell_instance constraint    pattern scope
//    value   name  position      name     properties
// ---------- ----- -------- ------------- ---------- -------------------
//     CO     chain1    5                  (Dynamic)  Scan Patterns only
//     OX     chain4    7    /reg_d2_/Q    (Dynamic)  Chain + Scan Patt's
```

Example 2

The following example constrains all the remaining scan cells in the chain1 scan chain to a constant one:

add_cell_constraints -chain chain1 c1

Example 3

The following example solves C6 rule violations resulting from DRC:

add_cell_constraints -drc c6

Example 4

The following example adds an OX constraint to all flip-flops controlled by clock /clk1:

add_cell_constraints -clock /clk1 -type flop 0x

add_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

add_cell_models ***dftlib_model*** {**-TYPE** {**INVerter** | **AND** | **BUFfer** | **OR** | **NAND** | **NOR** | **XOR** | **CLOCK_BUFfer** |{**MUX** ***mux_select mux_in0 mux_in1***}
| {**SCAN_CELL** ***clock data*** [-POSEDGE_clock | -NEGEDGE_clock]}
| {**DFF** ***clock data*** [-POSEDGE_clock | -NEGEDGE_clock]}
| {**LATCH** ***enable data*** [-ACTIVE_HIGH_clock | -ACTIVE_LOW_clock]}

Description

Specifies DFT library models for user-defined test points, system-generated test points, and system-generated test logic.

When adding test logic circuitry, multiple models from the DFT library are used. The cell_type attribute in the library model description specifies the components available for use as test logic. You can use the add_cell_models command instead of defining the cell_type attribute in the library model description.

For more information on the design library attribute, see cell_type in the *Tessent Cell Library Manual*.

Note

The add_cell_models command does not recognize `celldefine cells as library cells and issues an error stating that these cells are not found in the library.

Arguments

- ***dftlib_model***

  A required string that specifies the name of a cell model in the DFT library used for test logic, buffer tree, lockup cell, or test point insertion.

- **-TYPE**

  A required switch and argument pair that specifies a model type. Options include:

  INVerter — a literal specifying a 1-input inverter cell.

  AND — a literal specifying a 2-input AND cell.

  BUFfer — a literal specifying a 1-input buffer cell.

  OR — a literal specifying a 2-input OR cell.

  NAND — a literal specifying a 2-input NAND cell.

  NOR — a literal specifying a 2-input NOR cell.

  XOR — a literal specifying a 2-input exclusive OR cell.

CLOCK_BUFfer— a literal specifying a clock buffer cell.

MUX ***mux_select mux_in0 mux_in1*** — a literal and three strings specifying a 2-1 multiplexer and the names of the selector pin and both data pins.

SCAN_CELL ***clock data*** [-POSEDGE_clock | -NEGEDGE_clock] — a literal and two strings specifying one of the following scan cells:

- a mux-DFF scan cell with the following four input pins: clock, data, scan in, and scan enable
- a clocked-scan cell with the following four inputs: clock, data, scan clock, and scan enable
- a LSSD scan cell with the following five inputs: clock, data, scan in, master clock, and slave clock

You must specify the name of the clock and data pins of the DFT library cell model. You may also include an optional switch to specify the inversion on the clock pin. This option works in conjunction with the add_tied_signals and the set_registered_io commands.

DFF ***clock data*** [-POSEDGE_clock | -NEGEDGE_clock] — a literal and two strings specifying a D flip-flop with two input pins, specifically, clock and data. You must specify the names of the clock and data pins of the DFT library cell model. This option works in combination with the add_tied_signals command or set_lockup_cell command. If you are defining this model for use with lockup cells, you may also use an optional switch to specify the overall inversion on the clock pin.

LATCH ***enable data*** [-ACTIVE_HIGH_clock | -ACTIVE_LOW_clock] — a literal and two strings specifying a D latch with two input pins, specifically enable and data. You must specify the names of the enable line and the data pin of the DFT library cell model. If you are defining this model for use with lockup cells, you may also use an optional switch to specify the overall inversion on the clock pin. If you use this command to add an active_low latch, you must specify "add_cell_models *dftlib_model* -type latch *enable data* -active_low". The default is -active_high.

Example

The following example shows a typical use of test logic involving the set, reset, and clock pins on sequential elements (flip-flops). The tool can usually ensure controllability of sequential elements with model types of And, Or, and, Mux.

```
add_clocks 0 clk
set_test_logic -set on -reset on -clock on
set_system_mode analysis
report_dft_check
…
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux si a  b
```

add_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

Available when EDT is Off

add_chain_masks ***chain_name...*** [-Cell_constraints {OX | XX | TX}] [-Unload_value X]

Available when EDT is On

add_chain_masks ***chain_name...*** [-Cell_constraints {OX | XX | TX}]
[-Unload_value {X | 0| 1}]

Logic BIST simulation

add_chain_masks ***chain_name...*** [-Cell_constraints {OX | XX | TX}]
[-unload_value {0|1}] [-load_value {0|1}]

Description

Masks the load, capture, and/or unload values on the specified scan chains during simulation.

The add_chain_masks command allows you to mask specified scan chain values from the test results. This command also allows you to specify a circuit response (0/1) to the compactor ("dft -edt" context) or output pins ("patterns -scan" context). In addition, this command allows you to load a value (0/1) on the (internal) scan chain inputs when you need to disconnect the scan chain inputs from the PRPG and avoid filling the scan chain with X's.

You can use this command to specify that custom masking logic exists between the scan chain outputs and the compactor ("dft -edt" context) or between the scan chain outputs and output pins ("patterns -scan" context). You must create and appropriately control the custom masking logic.

Note that this command does not impact DI fault classification. You can manually change the DI fault classification using the reset_di_faults command.

Logic BIST simulation

Specifies the scan chains that are masked during fault simulation and their load and unload values. Used to work around design issues. You must use this command to specify the chains you want masked.

Arguments

- ***chain_name...***

  Required, repeatable string that specifies the name of a scan chain in the current design.

- -Cell_constraints OX | XX | TX

  Optional switch and literal pair that specifies the cell constraints and observe values for the masking of the specified scan chain(s).

OX — Load and capture values are applied, and the fault observation is not included in the results.

XX — Load and unload values are not applied, and values are captured normally for all scan cells in the scan chain for multiple-cycle tests.

TX — All scan cell values are tied as X.

- -Unload_value X | 0 | 1

  Optional switch and literal pair that specifies the unload value used to calculate the circuit response. Options include:

  X — Ties the unload value to X. This value is not valid for Logic BIST simulation.

  0 — Specifies the unload value is 0. This value valid only for EDT On, and for Logic BIST simulation.

  1 — Specifies the unload value is 1. This value alid only for EDT On, and for Logic BIST simulation.

- -Load_value 0 | 1

  Optional switch and literal pair that specifies the value that is applied to the (internal) scan chain input. You can use this switch only for designs that contain BIST logic. Options are:

  0 — Specifies the load value is 0.

  1 — Specifies the load value is 1.

Example 1

The following example does not apply load values (no controllability) or unload values (no observability) and uses all the cells from *chain1* during a multicycle test. The 0 unload value is used to calculate the circuit response for the external channels.

add_chain_masks chain1 -cell_constraints xx -unload_value 0

Example 2

This example shows the add_chain_masks in Context: pattern -scan. This command masks the scan chain input by loading a 0 and the scan chain output by unloading a 0 on chains chain1 and chain2. This data is transferred to pattern retargeting such that the chain mask register can be loaded with correct values to reflect this chain masking.

add_chain_masks chain1 chain2 -load 0 -unload 0

report_chain_masks

```
//  Masked scan chain  Load value  Unload value  Cell constraints
//  -----------------  ----------  ------------  ----------------
//        chain1            0            0              OX
//        chain2            0            0              OX
```

Related Command

add_clocks

Context: all contexts

Mode: setup

Usage

For all contexts other than “patterns -ijtag” and “dft -scan”

add_clocks [*off_state*] ***pin_pathname…*** [-Internal [-PIn_name *user_pinname*]]
[{-Free_running [-PEriod *time_value* [s | ms | us | ns | ps | fs] [-Divider *int*]]}
| -Always_capture]

For “patterns –ijtag” (extraction mode inactive)

add_clocks [*off_state*] ***primary_input_port…***
[-Free_running [-PEriod *time_value* [s | ms | us | ns | ps | fs] [-Divider *int*]]]

For “patterns –ijtag” (extraction mode active)

add_clocks [*off_state*] ***pin_pathname…***
[-Free_running [-PEriod *time_value* [s | ms | us | ns | ps | fs] [-Divider *int*]]]
[-Internal [-PIn_name *user_pinname*] -REFERENCE_PIN *port*
[-REFERENCE_PIN_Inv *port*] [-FREQ_Divider *pos_int*] [-FREQ_Multiplier *pos_int*]]

For “dft -scan” and “dft -test_points”

add_clocks [*off_state*] ***pin_pathname...*** [-Internal [-Top_name *existing_pin*] -Inverted]
[-Free_running] | [-Always_capture]

Description

Adds scan or non-scan clock pins to the clock list for proper scan operation. Any signal is considered to be a clock if it can change the state of a sequential element, including system clocks, sets, and resets.

Pins that you add to the clock list default to an off-state of 0. The off-state of a clock pin is the value on the pin that results in the clock inputs of sequential memory elements becoming inactive. For edge-triggered devices, the off-state is the value on the pin that results in placing their clock inputs at the initial value of a capturing transition. Set and reset lines are also considered as clock lines. You can constrain a clock pin to its off-state in order to suppress its use as a capture clock during the ATPG process. The constrained value must be the same as the clock off-state or an error occurs. If you add an equivalence to the clock list, all of its equivalent pins are added to the clock list as well.

Arguments

- *off_state*

  A optional literal that specifies the pin value that inactivates the sequential memory elements. The choices are:

  0 — A literal specifying the off-state value is 0 (default value).

1 — A literal specifying the off-state value is 1.

- ***pin_pathname***

  A required, repeatable string that typically lists the primary input pins to assign as clocks. The primary input pins in the list must have the same off_state. If the -Internal switch is used, pin_pathname lists internal pin pathnames. If both the -Internal and -Pin_name switches are used, pin_pathname lists internal pin pathnames to merge into a single, new primary input pin. The pin_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- ***primary_input_port***

  A required, repeatable string that lists the primary input ports to assign as clocks. The primary input ports in the list must have the same off_state.

- -Internal

  An optional switch that specifies that pin_pathname is an internal pin that, for ATPG purposes only, should be disconnected from its original driver and treated as if it were a clock primary input. If you use this switch, the pin_pathname argument must be an internal pin, not an actual clock primary input pin. When saving patterns, this internal clock input is not added to the top level interface. Use this switch to define internal clock inputs normally driven by on-chip circuitry.

Note

If you use the “write_patterns -Mode_internal” switch when saving serial or parallel simulation patterns, the test bench still forces the internal pins even though corresponding clock primary inputs are not included in the top-level interface. If you save the patterns using the -Mode_external switch, the test bench does not force those internal pins. In this case, unless the circuit generates values on the internal pins corresponding to what ATPG assumed was forced on the corresponding clock primary inputs, you may get simulation mismatches.

- -PIn_name *user_pinname*

  An optional switch and string pair that specifies the name for a new primary input clock pin that will drive all the internal pins specified with the pin_pathname argument. The user_pinname must be a single, simple name (wildcards are not allowed), which is given to the newly-created primary input pin. The -Pin_name switch is only allowed when the -Internal switch is also specified. The -Pin_name switch is also allowed if the pin_pathname argument specifies a single internal pin pathname and ensures a known pin name is used for the new primary input pin.

- -Free_running

  An optional switch that identifies the specified pin as a free-running clock. A free-running clock is pulsed during every cycle of every procedure. The clock you specify also pulses with any other clock, ignoring the specified clock restriction setting.

Free-running clocks are automatically pulsed in the external mode of named capture procedures (if present). Unless you define the free-running clock using the -Period switch, you must specify the clock in the internal mode of named capture procedures in order to simulate the effect of the clock pulses.

An always block is automatically created in the procedure file if it does not already exist, and the free-running clock is pulsed in this block. For more information, see "Always Block" in the *Tessent Cell Library Manual*.

- -PEriod *time_value* [s | ms | us | ns | ps | fs]

  An optional switch and real number pair that you can use only with the -Free_running switch. The time_value is a real number followed by an optional time unit that defaults to "ns." This switch specifies that the free-running clock is an asynchronous clock with a certain time period. Note that ATPG and DRC treat asynchronous free-running clocks as X values.

  The period of an asynchronous free-running clock can affect the timescale and precision of the Verilog testbench. For more information, refer to the description of the "set time scale" statement in the *Tessent Shell User's Manual*.

- -Divider *int*

  An optional switch and integer pair that can only follow the -Period switch. When using the -Divider switch, the -Period switch specifies a base period and the -Divider switch specifies the number of pulses to occur during the base period. The -Period switch and -Divider switch are intended for coherent clock groups, to specify the base period for a number of clock pulses and the total pulses during that base period. All clocks that share the same base period are grouped together as coherent clocks in the final Verilog testbench. For more information about using these two switches, refer to "Example 5" on page 421.

- -Always_capture

  An optional switch that identifies the specified pin as an always-capture clock. An always-capture clock is pulsed in every cycle of the capture window, except when using named capture procedures. The clock you specify also pulses with any other clock, ignoring the specified clock restriction setting.

- -REFERENCE_PIN *port* **(patterns -ijtag only)**

  Switch and string pair that is required when you specify the -internal switch in ICL extraction mode. The *port* argument specifies the source primary input port that is connected to the internal clock pin you specified with the *pin_pathname* argument.

- -REFERENCE_PIN_Inv *port* **(patterns -ijtag only)**

  An optional switch and string pair that specifies the second primary input port if the reference_pin is a differential pin.

- -FREQ_Divider *pos_int* **(patterns -ijtag only)**

  An optional switch and positive integer pair that defines the division factor of the clock frequency between the reference pin and the internal clock pin specified with the *pin_pathname* argument.

- -FREQ_Multiplier *pos_int* **(patterns -ijtag only)**

  An optional switch and positive integer pair that defines the multiply factor of the clock frequency between the reference pin and the internal clock pin specified with the *pin_pathname* argument.

- -Top_name *existing_pin* **(dft -scan only)**

  An optional switch and string pair that specifies the name of an existing top level pin that drives the internal node during scan chain shifting. The top level pin should be a clock signal; you do not need to define it using the add_clocks command. Note: Although the top_name switch is optional, the tool issues a warning message if it cannot automatically trace from the internal node to a primary input pin (the pin must not be a scan signal, and must not have any pin constraints).

- -Inverted **(dft -scan only)**

  An optional switch that must be used in conjunction with the -top_name switch to indicate an inverting path; this may be necessary if the signals cannot be traced due to a black-boxed module.

Example 1

The following example adds a clock to the clock list with an off-state of one, then adds an internal clock with an off-state of zero:

add_clocks 1 clock1
add_clocks 0 pll_block/clock1 -internal
report_clocks

Example 2

The following example adds an internal clock pin to a net, disconnecting the original driver of the net. This happens within the tool only; the tool does not modify the original source netlist. Then the example reports on the added clock pin and the original driver of the net. The example begins in Setup mode.

report_clocks

```
User-defined Clock (1):
 ---------  -----------  --------  ----  ----------------
 Off State  Constraints  Internal  Name  Other Properties
 ---------  -----------  --------  ----  ----------------
     0                      No     /clk
```

create_flat_model
report_gates /reg_d_1_7_/Q

```
//  /reg_d_1_7_   dff
//      CLK    I  /clk
...
//      Q      O  /ix225/A1
```

add_clocks 1 /ix225/A1 -internal

```
//  Warning: Flattened model deleted.
```

report_clocks

```
User-defined Clock (1):
 ---------  -----------  --------  ----  ----------------  ------
 Off State  Constraints  Internal  Name  Other Properties  Pin(s)
 ---------  -----------  --------  ----  ----------------  ------
     0                      No     /clk
     1                      Yes    /d_1_7_                 /ix225/A1
```

report_primary_inputs

```
USER:  /d_1_7_ (internal pin)
...
SYSTEM:  /clk
...
```

set_system_mode analysis
report_gates /d_1_7_

```
//  /d_1_7_  primary_input
//      d_1_7_  O  /ix225/A1
//
//  User-added pin driven by "/reg_d_1_7_/Q" in the source netlist.
```

report_gates /reg_d_1_7_/Q

```
//  /reg_d_1_7_  dff
//      CLK    I  /clk
...
//      Q      O
...
//
//  Gate drives user-added pin "/d_1_7_" in the source netlist.
```

Example 3

The following example adds a list of pathnames of internal clock pins to connect to the new primary input pin “div_pen” with an off-state of zero. An asterisk wildcard character is used in the example to only add pins with pathnames that end with divider_gate/CPEN.

add_clocks 0 *divider_gate/CPEN -internal -pin_name div_pen

Example 4

The following example specifies a free running clock named “sclk” with an off state of 0 and a total period of 40ns with a 50% duty cycle. In the Verilog testbench, the clock starts at time 0 in its off state:

add_clocks 0 sclk -free_running -period 40

Example 5

The following example specifies two free-running clocks that are coherent. The overall period for the coherent group is 1000ns. The clock “aclk” pulses 20 times during that period, while “bclk” pulses 30 times during that period, both with a 50% duty cycle:

add_clocks aclk -free_running -period 1000 ns -divider 20
add_clocks bclk -free_running -period 1000 ns -divider 30

The annotations and comments to document the free-running clocks in the pattern files occur in the header section of the pattern file right after the block of comments/annotations that are labeled “Begin_Verify_Section.” The annotations are grouped in a block with a begin and end annotation. Here is an example of the WGL block:

```
{  Begin_async_clocks }
{    sclk =  period: 100 ps  }
{  End_async_clocks }
```

If a timeplate name is used to specify the timing for the asynchronous clock, then additional information on the leading and trailing edge is also specified. If the -Divider switch is used, this is also present in the annotations:

```
{  Begin_async_clocks }
{    sclk = period: 100ps, leading: 40ps, trailing: 70ps }
{    aclk = period: 1000ns, divider: 20 }
{  End_asyn_clocks }
```

All other pattern formats use the identical block structure and syntax within the annotation or comment. The only differences are using the correct annotation or comment punctuation or statements surrounding this block.

Example 6

The following example works in “patterns -ijtag” only. The following commands produce an internal half-speed clock on the ICL module “chip” during ICL extraction:

set_design_sources -format icl -y icl_data
set_current_design chip
add_clocks { pll_block/clock1 } -internal -reference_pin clock1 -freq_divider 2
set_system_mode analysis

The resulting ICL created by the ICL extraction looks as follows:

```
Module chip {
   // Created by ICL extraction
   ClockPort clock1;
   …
   Instance block1_I1 Of block1 {
      InputPort ClkA = add_clock_inst_1.ClockOut;
       …
   }
   Instance add_clock_inst_0 Of chip_add_clock_0 {
      InputPort ClockIn = ClkA;
   }
}

// instanced as chip.add_clock_inst_0
Module chip_add_clock_0 {
   // Created by ICL extraction
   ClockPort ClockIn;
   ToClockPort ClockOut {
      FreqDivider 2;
      Source ClockIn;
```

```
        }
    }
```

add_config_element

Context: all contexts including unspecified

Mode: all modes

Usage

add_config_element [*name*] [-in_wrapper *wrapper_object*]
[-copy_from *config_object_spec*]
[-before *config_object_spec* | -after *config_object_spec* | -first | -last]
[-type wrapper | property]
[-value *value_list*]
[-replace]

Description

Adds a configuration element in the configuration tree.

The behavior of the command is different when adding an element inside a wrapper that fully defines the allowed child elements versus one which allows arbitrary elements. The allowed content of a wrapper is controlled by its metadata description. Wrappers of type single and simple properties exist automatically as soon as their parent wrapper is added. Therefore, these elements cannot be added using this command as they are automatically added when their parents are added. You use the set_config_value to specify their value.

You can add elements inside a parent wrapper that does not constrain its content (i.e. its metadata has the property AllowUnkown set to on), but you need to add everything inside it and define the type of object using the -type property. See Example 2 for an example that creates a configuration tree with no metadata.

Arguments

- *name*

  A string that specifies the name of the configuration element being added. When using the -in_wrapper option, the name is the relative pathname with respect to the specified wrapper. When not using the -in_wrapper option, the name is the complete pathname with respect to the root of the partition. The parent wrapper of the element must exist before the element can be added to it. For example DftSpecification(moda,rtl) must exist to add the IjtagNetwork wrapper into it using the “add_config_element DftSpecification(moda,rtl)/IjtagNetwork” command. The added element must not already exist unless the -replace option is used, in which case the existing element will be deleted before being added.

- -copy_from *config_object_spec*

  An optional option value pair used to specify that the added element is a copy of another one. When the allowed content of the destination parent wrapper is defined with Wrapper, the metadata definition of the source and destination element must be identical (i.e. both definitions must reference the same metadata definition). If this is not the case, an error message is generated. The name of the added element can be omitted when using both the -

copy_from and the -in_wrapper options. In this case, the parent wrapper of the copied element and the destination wrapper must be different. The element is added into the destination wrapper using the leaf_name of the copied object when the *name* option is not specified.

- -in_wrapper *wrapper_object_spec*

  An option value pair that specifies that the configuration element is to be added inside a specific wrapper. When the -in_wrapper option specified, the name option defines a name relative to the specified destination wrapper. The wrapper_object_spec can be the complete name of a wrapper relative to the root of the partition or a collection containing a single wrapper element as returned by get_config_elements or "get_config_value -object".

  The default partition defines wrappers by the name of tmp(*id*) which allow unknown elements to be added inside them. If you want to read an arbitrary configuration wrapper into the tool which does not match any defined syntax, you can use the "add_config_element tmp(*id*)" command to create an empty tmp wrapper. The *id* can be any arbitrary label and you can create as many tmp wrapper as you need. Once created, you can then use the "read_config_data file -in_wrapper tmp(*id*)" command to load arbitrary configuration data inside the tmp(*id*) wrapper. See Example 2 for an example of this usage.

- -before *config_object_spec*

  An optional option value pair that specifies a configuration element in front of which to add the new configuration element. When the -before option is used with a collection containing a configuration element object, the -in_wrapper option cannot be used as the parent wrapper is extracted from the object. Also, the name option must be a leaf_name with no hierarchical component.

  When the config_object_spec value is a name, it must be a name relative to the wrapper specified with the -in_wrapper option. If the -in_wrapper option is not specified, it is a name relative to the root of the partition.

  The -before option is mutually exclusive to the -after, -first, and -last options. When none of these four options is specified, -last is assumed.

- -after *config_object_spec*

  An optional option value pair that specifies a configuration element after which to add the new configuration element. When the -after option is used with a collection containing a configuration element object, the -in_wrapper option cannot be used because the parent wrapper is extracted from the object. Also, the name option must be a leaf_name with no hierarchical component.

  When the config_object_spec value is a name, it must be a name relative to the wrapper specified with the -in_wrapper option. It is a name relative to the root of the partition when the -in_wrapper option is not specified.

  The -after option is mutually exclusive to the -before, -first, and -last options. When none of these four options is specified, -last is assumed.

- -first

  An optional option that specifies to add the new configuration element before any other element in the parent wrapper.

  The -first option is mutually exclusive to the -before, -after, and -last options. When none of these four options is specified, -last is assumed.

- -last

  An optional option that specifies to add the new configuration element after all other elements in the parent wrapper.

  The -first option is mutually exclusive to the -before, -after, and -first options. When none of these four options is specified, -last is assumed.

- -type wrapper | data_wrapper | csv_wrapper | property

  An optional option value pair that is only needed and allowed when adding a configuration element for which no Wrapper exists. When adding an element for which metadata exists, the -type option is not allowed because the type of the object is specified in the metadata. When adding an element for which no metadata exists, the -type value defaults to “wrapper” when the -value option is not specified and to “property” when the -value option is specified.

  See Example 2 for an example of its usage when adding an element without metadata.

- -value *value_list*

  An optional option value pair that is used when adding a configuration element that needs a value. The -value option is typically needed when -type is specified as a property.

- -replace

  An optional option that suppresses the error that is normally generated when adding a configuration element with a name that conflicts with an existing element. The error only occurs if the element is defined as not repeatable in the metadata. Instead of an error, the existing element is first deleted.

Example1

The following example creates a DftSpecification using the add_config_element command. The generated configuration data is then reported.

```
> set_transcript_style input_only
> set spec    [add_config_element DftSpecification(moda,ex1)]
> set ijtag   [add_config_element IjtagNetwork -in $spec]
> set host    [add_config_element HostScanInterface(ijtag) -in $ijtag]
> set mbist   [add_config_element MemoryBist -in $spec]
> set_config_value ijtag_host_node -in $mbist HostScanInterface(ijtag)
> set ctl     [add_config_element Controller(c1)  -in $mbist]
> set step    [add_config_element Step -in $ctl]
> set mem_int [add_config_element MemoryInterface(m1) -in $step]
> set_config_value memory_library_name -in $mem_int ram12x4
> set mem_int [add_config_element ReusedMemoryInterface(m2) -in $step]
> set_config_value reused_interface_id -in $mem_int m1
> set step    [add_config_element  Step -in $ctl]
```

```
> set mem_int [add_config_element MemoryInterface(m3) -in $step]
> catch {set_config_value memory_library_name -in $mem_int ram12x8}
> set mem_int [add_config_element ReusedMemoryInterface(m4) -in $step]
> set_config_value reused_interface_id -in $mem_int m3
> report_config_data DftSpecification(moda,ex1)

DftSpecification(moda,ex1) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
    }
  }
  MemoryBist {
    ijtag_host_node : HostScanInterface(ijtag);
    Controller(c1) {
      Step {
        MemoryInterface(m1) {
          memory_library_name : ram12x4;
        }
        ReusedMemoryInterface(m2) {
          reused_interface_id : m1;
        }
      }
      Step {
       MemoryInterface(m3) {
          memory_library_name : ram12x8;
        }
        ReusedMemoryInterface(m4) {
          reused_interface_id : m3;
        }
      }
    }
  }
}
```

Example 2

The following examples adds a tmp wrapper which allows anything inside it to show how arbitrary configuration data can be created. Notice the use of the -type options when adding a data row and a csv row. The -type option is not needed when adding a wrapper or a property because it automatically defaults to wrapper or property based on the presence of the -value option.

```
> set tmp1  [add_config_element tmp(1)]
> set n_wpr [add_config_element NormalWrapperExmaple(abc) -in $tmp1]
> add_config_element -in $n_wpr prop_example -value [list a b c]
> set d_wpr [add_config_element DataWrapperExample -in $n_wpr]
> # -type is needed otherise it would default to property as
> # -valus is not specified
> add_config_element -in $d_wpr element1 -type property
> add_config_element -in $d_wpr element2 -value 32ns
> set c_wpr [add_config_element CsvWrapperExample -in $n_wpr]
> add_config_element -in $c_wpr -value [list a b c]
> add_config_element -in $c_wpr -value [list d e]
> add_config_element -in $c_wpr -value [list f g h] -after <0>
> report_config_data $tmp1

tmp(1) {
```

```
    NormalWrapperExmaple(abc) {
      prop_example : a, b, c;
      DataWrapperExample {
        element1;
        element2 : 32ns;
      }
      CsvWrapperExample {
        a, b, c;
        f, g, h;
        d, e;
      }
    }
  }
```

add_config_message

Context: all contexts

Mode: all modes

Usage

add_config_message **-config_object** ***config_object message***
[-error | -warning | -info]
[-display]

Description

Adds error, warning, or information messages to configuration elements.

Arguments

- **-config_object** ***config_object message***

  A required value that specifies the configuration object to which to add the message specified by the message string. The config_object value is the name of a configuration element or a collection containing a single configuration element object.

- -error

  An optional Boolean option that specifies that the messages to be added are of type error.

- -warning

  An optional Boolean option that specifies that the messages to be added are of type warning.

- -info

  An optional Boolean option that specifies that the messages to be added are of type info.

- -display

  An optional option that specifies to also display the error, warning, or information messages in the transcript. Without this option, the message is silently added to the configuration object.

Example

The following example adds an error message to a property element. The -display option specifies to also report the error message in the transcript window.

```
> add_config_message -config_object /tmp(1)/propertyA -error -display \
"The value A is inconsistent with the design level '[get_design_level]'."
```

add_config_tab

Context: all contexts

Mode: all modes

Usage

add_config_tab ***wrapper***

Description

Adds one or many configuration tree tabs in the DFTVisualizer Configuration Data window.

Arguments

- *wrapper*

  An optional value that specifies the name of the configuration wrapper. The value is either the name of a wrapper, a Tcl list of names of wrappers, or a collection containing one or more configuration wrappers. The wrappers are the root wrapper displayed in the tab.

Example

This example displays a tcd_memory wrapper in the Configuration Data window. Notice the use of the get_config_element command to obtain the configuration object. The name could not be used directly in the add_config_tab the tool only looks in the default partition. The display_specification command adds a DftSpecification into the Configuration Data window.

```
> add_config_tabs [get_config_element Core(RAM12x8) -partition tcd]
```

add_control_points

Context: dft -test_points

Mode: setup, analysis

Usage

add_control_points **-location** ***pin/port_spec*** -type {**AND** | **OR**}
[-scan_cell_clock ***clock_pin/port***]
[-enable ***enable_pin/port***]

Description

Specifies user-defined control points during test point insertion.

Arguments

- **-location** ***pin/port_spec***

  A required switch and string that specifies the pathname to the control point location.

  The ***pin/port_spec*** can be the name of a pin/port, a Tcl list of pins/ports, or a collection of pin/port objects.

- **AND | OR**

  A required literal that specifies the gate type to be inserted at the control point location.

- -scan_cell_clock ***pin/port_spec***

  An optional switch and string pair that specifies the path name of the clock signal used to clock the control point. This can be a collection or list, but should have only one element.

- -enable ***pin/port_spec***

  An optional switch and string pair that specifies the path name of an existing net used to enable/disable the control point. This can be a collection or list, but should have only one element.

Example 1

The following example adds a type OR control point and a type AND control point. For the AND control point it also specifies the path name of the clock signal used to clock the control point:

```
add_control_point -location gc[1] -type OR
add_control_point -location gd[1] -type AND -Scan_cell_clock gclk4
report_test_points
```

Example 2

The following example specifies the path name of an existing net that is to be used to enable/disable the control points. For the AND control point it also specifies the path name of

the clock signal used to clock the control point. Then it proceeds to insert the control points into the netlist:

```
set_test_point_insertion_options -control_point_enable cp_enable
add_control_point -location ga[1] -type OR -Scan_cell_clock buf1/Z
report_test_points
...
set_system_mode analysis
...
insert_test_logic
```

add_core_instances

Context: patterns -scan, patterns -scan_retargeting

Mode: setup

Usage

add_core_instances **-core *core_name*** [-mode *mode_name*]
{**-modules *module_objects*** | **-instances *instance_objects*** | **-current_design**}
[-silent]

Description

Adds a core instance to the design by associating/binding the core description currently in memory with the specified core instance(s) in the design.

The read_core_descriptions command must have already been executed before using this command.

You can specify the core(s) with which to associate the core description with by providing either absolute instance pathnames to the cores or uniquified module names, or by using the -current_design switch.

Arguments

- **-core *core_name***

  A required switch and Tcl list that specifies the core name of the core description from which the instantiation should take place.

- -mode *mode_name*

  An optional switch that specifies the mode of the core. This switch is required if the core has multiple modes.

- -modules *module_objects*

  A required switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. The core instances are created for each instantiation of those objects in the design.

- -instances *instance_objects*

  A required switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. The core instances are created for each instance in the list.

- -current_design

  A required switch that specifies to add the core instance with respect to the current design. This switch is mutually exclusive with the -modules and -instances switches. The mode of the core instance being added must be different than the mode of the current design.

- -silent

  An optional switch that specifies to suppress warning messages.

Example 1

The "Retargeting Example" in the *Tessent Scan and ATPG User's Manual* demonstrates the use of this command in a design context.

Example 2

The following example demonstrates the use of the -current_design switch to merge two modes of a core; in this case, the "core" is the top level. In the example, patterns are generated separately for two sub-blocks of a design from the top level pins. Sub-Block1 is tested as mode M1 of the top level, and Sub-Block2 is tested as mode M2 of the top level. The result, shown in Figure 7-1, is the merging of the two pattern sets originally generated for each individual mode into a single pattern set applied at the top level.

The first dofile reads in the top level design and writes out the patterns and core description files for mode M1 targeting Sub-Block1:

```
// Invoke tool to generate patterns for each mode of top_level
set_context pattern -scan
read_verilog top_level.v                    // Read netlist of top_level

// Mode M1 consists of the Sub-Block1 design; the user must blackbox Sub-Block2 and apply
// constraints to access Sub-Block1
set_current_mode M1 -type internal
...
set_system_mode analysis
...
create_patterns
write_patterns top_levelM1.ascii
write_core_description top_levelM1.tcd
```

The second dofile reads in the design and writes out the patterns and core description files for mode M2 targeting Sub-Block2:

```
// Mode M2 consists of the Sub-Block2 design; the user must blackbox Sub-Block1 and apply
// constraints to access Sub-Block2
set_current_mode M2 -type internal
...
set_system_mode analysis
...
create_patterns
write_patterns top_levelM2.ascii
write_core_description top_levelM2.tcd
```

The third dofile merges the two separately generated top-level pattern sets (modes M1 and M2) into a single pattern set:

```
// Invoke the tool again to retarget patterns to top level
set_context patterns –scan_retargeting
...
read_core_description top_levelM1.tcd
read_core_description top_levelM2.tcd
add_core_instance –core top_level –mode M1 –current_design
add_core_instance –core top_level –mode M2 –current_design
set_system_mode analysis

// Mode extracted from ASCII file
read_patterns top_levelM1.ascii
read_patterns top_levelM2.ascii
write_patterns ...
```

Figure 7-1. Merging Patterns for Multiple Views of a Core at the Top Level

Example 3

The following example demonstrates the use of the add_core_instances -current_design switch to merge mode M1 of the current design and mode internal of CoreB. In the example, one pattern set is generated at the top level (mode M1 of the top level) to test Sub-Block1, and a second pattern set is generated at the core level of CoreB. The result, as shown in Figure 7-2, is the integration of the two pattern sets, originally generated for mode M1 of the top level and mode internal of CoreB, into the top level.

The first dofile reads in the top level design and writes out the patterns and core description files for mode M1 targeting Sub-Block1.

```
// Invoke tool to generate patterns for mode M1 of the top level
set_context pattern -scan
read_verilog top_level.v                    // Read netlist of top_level

// Mode 1 consists of the Sub-Block1 design; the user must blackbox any other blocks not
// targeted, and apply constraints to access Sub-Block1
set_current_mode M1 -type internal
...
set_system_mode analysis
...
create_patterns
write_patterns top_levelM1.ascii
write_core_description top_levelM1.tcd
```

The second dofile reads in the CoreB design and writes out the patterns and core description files.

```
set_system_mode setup
delete_design
read_verilog CoreB.v
set_current_mode internal -type internal
...
set_system_mode analysis
create_patterns
write_patterns CoreB.ascii
write_core_description CoreB.tcd
```

The third dofile merges the top level pattern set (mode M1) with the retargeted CoreB patterns.

```
// Invoke tool to retarget patterns to top level
set_context patterns –scan_retargeting
...
read_core_description top_levelM1.tcd
read_core_description CoreB.tcd
add_core_instance -core top_level -mode M1 -current_design
add_core_instance -core CoreB -mode internal -instances  /CoreB_i
...
set_system_mode analysis
read_patterns top_levelM1.ascii
read_patterns CoreB.ascii
write_patterns  ....
```

add_display_data

Context: all contexts

Mode: setup, analysis

Usage

add_display_data {
Error_pattern | **PATtern_index** ***pattern_index*** [-Internal | -External] |
Parallel_pattern ***pattern_number*** (0..31)| **Fault_status** | **TIe_value** |
COnstrain_value | **Seq_depth_data** | **CLock_cone** ***pin_name*** |
CAPTURE_PROCedure ***procedure_name*** |
Drc_pattern {{**Test_setup** [{{-Cycle | -Time} *n1*} [*n2* | End]]} | **Load_unload** | **SHIft** |
SKew_load | **SHADOW_Control** | **Master_observe** |
SHADOW_Observe | **STate_stability** | **TEST_End [***time* | -All**]**}}

Note

The following DFTVisualizer menu paths are available when the associated data or procedure is available; so you may not see all these selections all the time.

Possible DFTVisualizer Menu Paths:
Data > Capture Procedure | Test-Setup | Load-Unload | Shift | State-Stability | Error Pattern | Pattern Index | Parallel Pattern | Fault | Tied | Constrain | Sequential Depth | Clock Cone | Test-End

Note

The following arguments are not supported in dft -scan: Pattern_index, Parallel_pattern, Fault_status, and Seq_depth_data.

Description

Adds specified data columns to the Data window of DFTVisualizer, opening the Data window if it is not already open. If data corresponding to an added column is available, it is displayed.

The command's arguments and usage are based on the set_gate_report command and control the types of data displayed similar to how the set_gate_report command controls the data output of the report_gates command.

If a column has been added and then removed during a tool session, you can re-add it by moving the cursor to the column title bar, then using the right mouse button popup menu to reselect the column for display.

Use the delete_display_data command (or the right mouse button popup menu) to remove data columns you no longer need.

Arguments

For complete detailed descriptions of the type of data that the arguments control, refer to the similar arguments listed in the set_gate_report command description.

Examples

The following example adds a column displaying the simulated values for cycles 5 through 10 of the test_setup procedure:

```
add_display_data drc_pattern test_setup -cycle 5 10
```

add_display_instances

Context: all contexts

Mode: setup, analysis

Usage

add_display_instances {{***gate_id#*** [-Pin *pin_name*] | ***pin_pathname*** | ***instance_name***
[-Pin *pin_name*] | **-PAth** ***start end***}}...}
[-Backward [-One | -End_point] | -Forward [-One | -All | -End_point] | -Up | -DOwn]
[-DIsplay {DEBug | DESign | DAta | WAve | HIerarchy | LIbrary | ALl}]

Description

Displays instances in DFTVisualizer and enables you to trace visually through the design using the Debug or Design window.

The add_display_instances command has two purposes:

- Adds display instances to DFTVisualizer windows

  How DFTVisualizer updates the display in the Debug window when you add an instance depends on the gate level that is in effect, as summarized in the following table:

  Table 7-5. How the DFTVisualizer Debug Window Displays Instances

Gate Level of Instance You Specify	"set_gate_level Design" in effect	"set_gate_level Primitive" in effect
Primitive	Displays the design level instance of which the primitive is a part	Displays the primitive
Design	Displays the design level instance	Displays all the primitives in the design level instance

- Traces visually through the design

  Tracing is the process of displaying additional gates that are connected to an already displayed gate. You might want to trace in order to expand the schematic view, gain insight into circuit behavior, or get oriented within a large design. In the Debug window, you can trace from a displayed instance forward towards the primary output pins or backward towards the primary input pins at the gate level currently specified by the set_gate_level command. In the Design window, you can additionally trace from a displayed instance up or down the design hierarchy.

Arguments

The following arguments describe the methods for naming the instances you want DFTVisualizer to display. You can specify any number of these five arguments, in any order.

- ***gate_id#***

  A repeatable integer and optional switch and string pair that specifies a gate to display in DFTVisualizer. The value of the *gate_id#* argument is the unique identification number the tool automatically assigns to every gate within the design during the model flattening process.

- ***pin_pathname***

  A repeatable string that specifies the pin pathname (<instance pathname>/<pinname>) of a pin within the design. DFTVisualizer displays the gate associated with that pin.

- ***instance_name***

  A repeatable string that specifies the instance pathname of an instance within the design. DFTVisualizer displays the gate associated with that instance. You can include any number of asterisks (*) or question marks(?) as wildcard characters to specify this string enabling you to match many pathnames in the design.

Note

For the Design and Data windows, *instance_name* can also be a hierarchical submodule. For the Debug window, *instance_name* must be a design level instance.

- **-Path** ***start end***

  A repeatable switch and two-string triplet that specifies to display all gates in the circuit path beginning at the *start* gate and ending at the *end* gate. Start and end can be a *gate_id#* or *pin_pathname*.

Note

When this switch is specified in the Design window, the tool attempts to trace the path in one direction beginning at *start* gate; the tool returns an error if *end* gate is not found. In the Debug window, the tool first attempts to trace the path in the direction specified by the user. If that path is not found, the tool then attempts to trace the path in the opposite direction. If that path in not found, the tool returns an error message.

- -Pin *pin_name*

  An optional switch and string pair that specifies a particular input or output pin of the specified gate or instance.

The next four switches determine the direction you want the tool to trace from the specified gate(s):

Note

The trace switches are not supported in the Data window.

- -Backward

  An optional switch that specifies to trace from the given instances backward, towards the primary input pins.

  If you do not explicitly specify a stopping point switch (-One, -End_point) in combination with this switch, the command default is for the backward trace to include only *one* level of gates (Debug window) or one hierarchal instance (Design window).

- -Forward

  An optional switch that specifies to trace from the given instances forward, towards the primary output pins.

  If you do not explicitly specify a stopping point switch (-One, -End_point, or -All) in combination with this switch, the command default is for the forward trace to include only *one* level of gates (Debug window) or one hierarchical instance (Design window).

- -Up

  An optional switch that specifies for DFTVisualizer to trace up one level of hierarchy from the given instance(s). This switch is not valid for the Debug window.

- -DOwn

  An optional switch that specifies for DFTVisualizer to trace down one level of hierarchy from the given instance(s). This switch is not valid for the Debug window.

Each of the following optional switches determine the stopping point for a trace by specifying the last gate you want DFTVisualizer to include in the display. If used, select just one to include in the command string.

- -One

  An optional switch whose behavior depends on whether you are doing a backward trace or a forward trace, as follows:

  Backward trace — Display only the first gate backward from a specified input pin (or from each input pin of a specified instance) from which you are tracing. This is the default for a backward trace.

  Forward trace — Display only one fanout gate connected to a specified output pin (or connected to each output pin of a specified instance) from which you are tracing, even if the pin fans out to multiple gates.

  This switch must be accompanied by the -Forward or -Backward switch.

- -End_point

  An optional switch that specifies to continue the trace until reaching either a primary input, primary output, tie gate, memory, or sequential element (latch or flip-flop, scan or nonscan). This switch must be accompanied by the -Forward or -Backward switch.

  This switch currently is not supported in the Design window.

- -All

  An optional switch that, together with the -Forward switch, specifies to trace to all the fanout gates connected to an output pin from which you are tracing. This switch must be accompanied by the -Forward switch.

- -Display *window_name*

  An optional switch and repeatable literal that specify the DFTVisualizer windows to which the tool should add instances and data sets if available. The valid options for the *window_name* argument, from which you can select as many as you want, are as follows:

  DEBug
  A literal that specifies the Debug window.

  DESign
  A literal that specifies the Design window.

  DAta
  A literal that specifies the Data window.

  WAve
  A literal that specifies the Wave window.

  HIerarchy
  A literal that specifies the Hierarchy window.

  LIbrary
  A literal that specifies the Library window.

  ALl
  A literal that specifies all the preceding windows.

  The default is to add instances to the Debug window only.

Examples

The following example opens DFTVisualizer if not already open and displays a single gate in the Debug window by specifying the gate identification number (51):

```
add_display_instances 51
```

The next example specifies for the tool to additionally display all the gates in the first level of fanout from the Q output of gate 51. Gates connected directly to the Q output comprise the first level of fanout gates. (Gates fed by the first level of fanout gates comprise the second level of fanout gates and are not displayed.)

```
add_display_instances 51 -pin Q -forward -all
```

The next example clears the schematic display of all gates, then creates a new display that shows the specified gate, along with a backtracking of all the gates until the trace reaches either a primary input or tie gate.

```
delete_display_instances -all
add_display_instances 51 -backward -end_point
```

add_edt_blocks

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Usage

add_edt_blocks ***block_name***

Description

Creates an arbitrary identifier for an EDT block and applies certain subsequent commands only to that block.

This command defines a string, referred to as the block name or block tag, as the identifier for an EDT block instantiated in a design netlist and simultaneously restricts the applicability of certain subsequent commands to that block. Restricting the applicability of these commands to a particular EDT block is referred to as setting or changing the EDT context, and the EDT block on which context-sensitive commands currently operate is referred to as the current EDT block. The current EDT block remains the sole target of the context-sensitive commands until you delete its definition using the delete_edt_blocks command or change the context to a different EDT block using set_current_edt_block or another add_edt_blocks command.

You must use this command to define a unique name for an EDT block prior to defining its attributes using context-sensitive commands. The add_scan_chains command, EDT-specific commands that define attributes for a given block, and some reporting commands are presently the only context-sensitive commands. All other commands (set_system_mode, create_patterns and report_statistics for example) apply to the entire netlist.

If multiple EDT blocks are defined and none of them is specified as the current EDT block, subsequent context-sensitive commands that define attributes for a given block ("set_edt_options -channels" for example) returns an error. This can happen if you add multiple EDT blocks, then delete the one that is the current EDT block.

For more information about EDT blocks or the modular Tessent TestKompress flow, refer to the "Modular Compressed ATPG" chapter of the *Tessent TestKompress User's Manual*.

Arguments

- ***block_name***

  A required string that specifies a name to use for uniquely identifying a specific EDT block instantiated within a netlist. You can use any unique name you like, as it is independent of the module and instance names used in the netlist.

Example 1

The following example defines the block name, "my_core1_block" for an EDT block that contains four scan chains. The tool determines the EDT block to associate with this name from

the pin pathnames specified in the add_scan_chains commands that follow the add_edt_blocks command.

add_edt_blocks my_core1_block

```
# my_core1_block is the current EDT block.
```
...

add_scan_chains -internal core1_chain1 grp1 /edt_top_core1/cpu1_i/edt_si1
/edt_top_core1/cpu1_i/edt_so1
add_scan_chains -internal core1_chain2 grp1 /edt_top_core1/cpu1_i/edt_si2
/edt_top_core1/cpu1_i/edt_so2
add_scan_chains -internal core1_chain3 grp1 /edt_top_core1/cpu1_i/edt_si3
/edt_top_core1/cpu1_i/edt_so3
add_scan_chains -internal core1_chain4 grp1 /edt_top_core1/cpu1_i/edt_si4
/edt_top_core1/cpu1_i/edt_so4

Example 2

The following example defines two more block names, “my_core2_block” and “my_core3_block”, then displays a list of the current block names. The display indicates subsequent context-sensitive commands will apply only to the EDT block named “my_core3_block”.

add_edt_blocks my_core2_block

```
# my_core2_block is the current EDT block.
```
...
add_scan_chains -internal core2_chain1 grp1 /edt_top_core2/cpu3_i/edt_si1
/edt_top_core2/cpu3_i/edt_so1
add_scan_chains -internal core2_chain2 grp1 /edt_top_core2/cpu3_i/edt_si2
/edt_top_core2/cpu3_i/edt_so2
...

add_edt_blocks my_core3_block

```
# my_core3_block is the current EDT block.
```
...
add_scan_chains -internal core3_chain1 grp1 /edt_top_core3/cpu7_i/edt_si1
/edt_top_core3/cpu7_i/edt_so1
...
add_scan_chains -internal core3_chain8 grp1 /edt_top_core3/cpu7_i/edt_si8
/edt_top_core3/cpu7_i/edt_so8

report_edt_blocks

```
//  my_core1_block
//  my_core2_block
//  my_core3_block   (current block)
```

Example 3

The following example removes from the tool's internal database, the data for the EDT block named "my_core3_block", making it unavailable for use with the set_current_edt_block command.

delete_edt_blocks my_core3_block

```
// Block deleted. No EDT block now selected as current block.
```

report_edt_blocks

```
//  my_core1_block
//  my_core2_block
```

Related Commands

delete_edt_blocks
report_edt_blocks
set_current_edt_block

add_edt_configurations

Context: dft -edt

Mode: setup

Usage

add_edt_configurations ***config_name***

Description

Sets up EDT logic with two compression configurations.

The add_edt_configurations command creates a compression configuration and applies subsequent EDT channel specifications to the configuration. Up to two compression configurations can be defined for a design block.

In a multi-block design flow, you can define the compression configurations at the top-level integration and all subsequently added blocks inherit the defined compression configurations. The configuration parameters need to be set for each block context.

Note

When two configurations are specified and one of the configurations is missing an input/output channel parameter, it inherits the needed value from the other configuration. You can override this feature by explicitly specifying the channel configuration.

For more information on setting up two compression configurations, see the "Defining Dual Compression Configurations" section in the *Tessent TestKompress User's Manual*.

Arguments

- ***config_name***

  A required string that specifies a name for the compression configuration.

Example

The following example shows a dofile that creates two configurations for a single block.

```
# edt_ip_creation.do
#
# Dofile for EDT logic creation
dofile scan_chain_setup.dofile

# Set up EDT configurations
set_edt_options -location internal
add_edt_configurations my_sys_test_config
set_edt_options -input_channels 4 -output_channels 2
add_edt_configurations my_wafer_test_config
set_edt_options -input_channels 5 -output_channels 4

# Set bypass pin
set_edt_pins bypass my_bypass_pin
```

```
# Set edt configuration pin
set_edt_pins configuration my_configuration_pin
set_system_mode analysis

# Report and write EDT logic.
report_edt_configurations -all # Report configurations for all blocks.
report_edt_pins # Report all pins including compression configuration
# specific pins.
write_edt_files created -verilog -replace # Create dofiles and
# test procedure files for both the configurations and the bypass mode
write_design -output_file created_edt_top_rtl.v -replace # Write the
# current design in Verilog format to the file created_edt_top_rtl.v.
```

Related Commands

delete_edt_configurations
report_edt_configurations
set_current_edt_configuration

add_edt_connections

Context: dft -edt

Mode: setup

Usage

add_edt_connections {[-Signal ***type*** {-To *connection_pathname* | -No_connection}] [-Blocks {*block_name*...} | -All_blocks]} [{-From *connection_pathname*} {-To {*connection_pathname*...}}]

Description

Specifies EDT logic connections for the block-level design flow.

Use this command to specify the connections needed during the integration of EDT logic blocks into the top-level netlist as follows:

- Top-level connections for the EDT control signals
- Other connections between pins/nodes in the design

For information, see "Creating the Top-level Netlist" in the *Tessent TestKompress User's Manual*.

If the *-signal* switch is specified as *scan_enable* or *-signal* is not specified at all, the tool uses simulation to virtually resolve the stitching of a pin at the top level to the block level by identifying a source and sink node. Typically, the source node is an internal connection node, and the sink node is the block port that corresponds to the block-level signal.

When test procedures are simulated, the events on the top-level signals are simulated and the event propagates to the internal connection node (source). (Note that this event propagation path may have inverters/buffers.) When an event is detected on the internal connection node (source), a corresponding event is scheduled on the sink node; this mimics a virtual wire connection between the source and sink that is not present during the integration phase but will be present during the pattern generation phase when EDT connections are physically materialized.

For example, a T3 DRC violation would normally occur when stitching the scan enable at the top level because the scan enable would only be stitched after DRC. Simulation avoids the T3 violation by allowing the block-level scan enable port to be driven correctly and scan chain tracing will pass.

Arguments

- -Signal ***type***

  An optional switch and literal pair that specifies an EDT control signal. Valid literals include:

  clock — specifies the edt_clock pin.

reset — specifies the edt_reset pin.

scan_enable — specifies the top-level scan_en pin.

bypass — specifies the edt_bypass pin.

update — specifies the edt_update pin.

configuration — specifies the edt_configuration pin for dual configuration applications.

master_clock — specifies the master_clock pin. Use in latch-based EDT logic for LSSD designs only.

slave_clock — specifies the slave_clock pin. Use in latch-based EDT logic for LSSD designs only.

input_channel *N* — appended with the channel number to specify an EDT input channel.

output_channel *N* — appended with the channel number to specify an EDT output channel.

single_bypass_chain — edt_single_bypass_chain pin.

low_power_shift_en — low power shift enable pin for low-power decompressor.

- -To *connection_pathname...*

  Optional switch and repeatable string pair that specifies the pathname of the destination pin/node for a connection. The connection_pathname can be an existing top-level pin, a new top-level pin, or an internal node. Multiple destination pins can be specified for non-EDT pin connections.

- -From *connection_pathname*

  Optional switch and string pair that specifies the pin pathname of the source pin/node for a non-EDT connection. The connection_pathname can be an existing top-level pin, a new top-level pin or an internal node.

- -No_connection

  Optional switch that specifies no connection for an EDT pin.

- -Blocks *block_name***...**

  Optional switch and repeatable string pair that specifies one or more blocks. If no blocks are specified, the current one is assumed.

- -All_blocks

  Optional switch that specifies all blocks. If no blocks are specified, the current one is assumed.

Example

The following example integrates two blocks, B1 and B2, and connects a non-EDT pin to test_en.

Add top-level clocks/pin constraints and test procedure file:

```
add_scan_groups grp1 top.testproc
add_clocks 0 clk1 clk2
```

Turn on EDT mapping to enable reading block level dofiles:

```
set_edt_mapping on
```

Add the EDT blocks:

```
add_edt_blocks B1
set_edt_instances -block_location B1_inst
dofile B1_edt.dofile
add_edt_blocks B2
set_edt_instances -block_location B2_inst
dofile B2_edt.dofile
```

Specify connections to block-level EDT signals:

```
add_edt_connections -signal input_channel 1 -to TK_channel_in[0] -block B1
add_edt_connections -signal output_channel 1 -to TK_channel_out[0] -block B1
add_edt_connections -signal input 1 -to TK_channel_in[1] -block B2
add_edt_connections -signal output 1 -to TK_channel_out[1] -block B2
add_edt_connections -signal clock -to TK_clk -blocks B1 B2
add_edt_connections -signal update -to TK_upd -all_blocks
add_edt_connections -signal bypass -to /tap_i/tap_ctrl_i/edt_bypass_inst -all_blocks
```

Optionally, specify a connection for a non-EDT signal:

```
add_edt_connections -from tap_i/tap_ctrl_i/test_en \
-to /B1_inst/test_en /B2_inst/test_en
```

Finally, change to analysis mode and make the specified pin connections:

```
set_system_mode analysis
report_edt_connections -all_blocks
write_edt_files integrate -replace
write_design -output_file integrate_edt_top_rtl.v -replace
```

Related Commands

delete_edt_connections

report_edt_connections

add_false_paths

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_false_paths
{[-From *source_node…* | -FROM_Clock *clock_signal_name…*]
[-TO *sink_node…* | -TO_Clock *clock_signal_name…*]
[{-THrough *through_node…*}…]} | **-CRoss_clock_domains**
[-Hold] [-Setup]

Description

Defines false paths in the design. False paths are paths that cannot be activated in the design's functional (at-speed) mode of operation. You would typically determine them as a part of static timing analysis, prior to ATPG.

If a false path is sensitized for an at-speed test during ATPG, incorrect capture responses can occur at certain scan cells and POs with resulting incorrect capture responses at the end points of the false path. This can cause simulation mismatches when you verify the patterns in a timing-based simulator. By defining the false paths, you enable the tool to identify the incorrect capture responses. Once identified, the tool will mask these responses (modify them to X) in the resultant patterns so they will not be the source of simulation mismatches.

For additional information, refer to "Preventing Pattern Failures Due to Timing Exception Paths," in the *Tessent Scan and ATPG User's Manual*.

Arguments

Tip: When using the following arguments, you can include any number of asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- -From *source_node…*

  An optional switch and repeatable string pair that specifies the starting point of a false path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified source node does not translate to an internal gate, the tool will transcript an error message and not add the false path definition to its internal database.

- -FROM_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the starting point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

  If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not add the false path definition to its internal database.

- -TO *sink_node…*

  An optional switch and repeatable string pair that specifies the end point of a false path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified sink node does not translate to an internal gate, the tool will transcript an error message and not add the false path definition to its internal database.

Note

For a 2-port latch with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “add_false_paths... -to CLK2” would define paths with an end point at D2.

- -TO_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the end point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

  If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not add the false path definition to its internal database.

- {-THrough *through_node…*}…

  An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the false path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

  When you use multiple -Through arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified path. For example, the following false path specification:

  add_false_paths -from A -through B C -through D E -to F

specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the -Through argument when specifying a path, the tool will consider all paths from the specified starting points to the specified end points to be false paths.

If a through node does not translate to an internal gate, the tool will transcript an error message and not add the false path definition to its internal database.

- **-CRoss_clock_domains**

  A switch that adds hold time false paths between all clocks.

Note

You cannot use this switch in Setup mode.

Use this switch instead of multiple add_false_paths command instances using the -TO_Clock and -FROM_Clock switches to specify each path and direction between the clocks. See Example 7.

- -Hold

  An optional switch that evaluates the false path for hold time violations.

- -Setup

  An optional switch that evaluates the false path for setup time violations.

  For more information, see "Types of Timing Exception Path Violations" in the *Tessent Scan and ATPG User's Manual*.

Example 1

The following example creates three false paths definitions, then reports all current false path definitions:

```
add_false_paths -from  /my_design/a  /my_design/b  -through  /my_design/u1
add_false_paths -to  /my_design/c
add_false_paths -through  /my_design/u24  /my_design/u25
report_false_paths -all
```

```
// False Path -from /my_design/a /my_design/b -through /my_design/u1
// False Path -to /my_design/c
// False Path -through /my_design/u24 /my_design/u25
// Total reported paths = 3
```

Example 2

The following example defines the path highlighted in Figure 7-3 as a false path:

```
add_false_paths -from  DFF1/q  -to  DFF5/d
```

Figure 7-3. Example of a False Path to be Defined

Here are four more ways you could define the same false path:

add_false_paths -from DFF1/q -through NOR1 -to_clock CLK

add_false_paths -from DFF1/clk -to DFF5/d

add_false_paths -from DFF1/q -to DFF5/clk

add_false_paths -from DFF1/clk -to DFF5/clk

Example 3

Referring to Figure 7-4, the following example defines as false paths all the paths that start from Reg_A[0...7] and end at Reg_B[0...3]:

add_false_paths -from Reg_A -to Reg_B

Figure 7-4. Example Circuit for Defining False Paths

Example 4

This example defines as false paths (in Figure 7-4) all the paths that start from Reg_A[0] and end at Reg_B[0...3]:

add_false_paths -from Reg_A[0] -to Reg_B

Example 5

This example defines as false paths all the paths that start from Reg_A[0] or Reg_A[3] and end at Reg_B[2]:

add_false_paths -from Reg_A[0] Reg_A[3] -to Reg_B[2]

Example 6

The remaining six examples describe signal matches for various sample pin pathnames specified using the asterisk (*) wildcard character. The pathnames are based on the following design:

```
module top(...);
   Input ...;
   Output...;
   ...
   foo u1(...);
   ...
endmodule;

module foo(...);
   Input...;
   Output...;
   ...
   staticRegister I_reg_1(.D1(...), .C1(...), .Z(...));
   staticRegister I_reg_2(.D1(...), .C1(...), .Z(...));
   staticRegister I_reg_3(.D1(...), .C1(...), .Z(...));
   staticRegister F_reg_1(.D1(...), .C1(...), .Z(...));
   staticRegister F_reg_2(.D1(...), .C1(...), .Z(...));
```

```
    ...
endmodule;
```

1. The signal name /u1/*reg_1/D1 will map to signals /u1/I_reg_1/D1 and /u1/F_reg_1/D1.
2. The signal name /u1/I_reg*/D1 will mapto signals /u1/I_reg_1/D1, /u1/I_reg_2/D1 and /u1/I_reg_3/D1.
3. The signal name /u1/*reg*/Z will map to signals /u1/I_reg_1/Z, /u1/I_reg_2/Z, /u1/I_reg_3/Z, /u1/F_reg_1/Z and /u1/F_reg_2/Z.
4. The signal name /u1/F_reg_2/* will map to signals /u1/F_reg_2/D1, /u1/F_reg_2/C1 and /u1/F_reg_2/Z.
5. The signal name /u1/F*/*1 will map to signals /u1/F_reg_1/D1, /u1/F_reg_1/C1, /u1/F_reg_2/D1 and /u1/F_reg_2/C1.
6. The signal name /u1/I*1/C1 will map to signal /u1/I_reg_1/C1.

Example 7

Assume the design contains two defined clocks: clk1 and clk2. The following command adds hold time false paths between clk1 and clk2:

add_false_paths -cross_clock_domains -hold

The above command is equivalent to the following two commands:

add_false_paths -from_clock clk1 -to_clock clk2 -hold
add_false_paths -from_clock clk2 -to_clock clk1 -hold

add_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Usage

add_fault_sites {**-ALl** | **-UNDEFINED_Cells**} [-VERBose]

Description

Automatically adds fault site definitions for library cells that don't have UDFM definitions.

The add_fault_sites command automatically adds port fault site definitions for library cells that are not covered by the current UDFM definitions so that you don't have to add them manually to the UDFM file. In order to distinguish those added definitions and resulting fault sites in report functions, the added definitions are collected in the UDFM type "auto-inserted-faults."

After you've added the fault sites, the add_faults command adds static or delay faults to those locations, as specified by the "set_fault_type udfm" command.

Note

The add_fault_sites command works only for the fault type UDFM, and is available only after you read a UDFM fault file and before you create the fault list.

For more information about UDFM, refer to "User-Defined Fault Modeling" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- **-ALl**

  A required switch that automatically adds UDFM definitions for all undefined (uncovered) port fault sites, including PI's and PO's. The fault sites affected by this switch include all those affected by the -Undefined_cell switch plus remaining port fault site definitions for existing cells and modules, as well as additional port fault sites without this scope.

- **-UNDEFined_cells**

  A required switch that automatically adds UDFM definitions for cell port fault sites in undefined (uncovered) cells or modules.

- -VERBose

  An optional switch that displays additional information about each added UDFM definition.

Example

The following example shows the effect of adding fault site definitions for all library cells not covered by UDFM definitions:

```
read_fault_sites /home/design/c090_std/c090_std.udfm
//  Reading UDFM File: /home/design/c090_std/c090_std.udfm
//     UDFM definitions read: Total=3, Cells=1, Modules=2, Instances=0, No Match=0
```

```
report_fault_sites -undefined_cells
//  Report of cells not defined by UDFM
//
//  Cell Name  Instances
//  ---------  ---------
//  M1               2
//  M2               1
//  u_mux2           1
//  ---------  ---------

add_fault_sites -undefined_cells
//  3 UDFM definition(s) for uncovered cells have been added
add faults -all
//  Number added faults=56  instances considered=7  not-considered=3
```

add_faults

Context: dft -edt, patterns -scan

Mode: analysis

Usage

add_faults ***fault_model_specific_options*** [*power_aware_options*]

Path Delay Faults Usage:
add_faults {***name_of_delay_path***… | **-All**} [-Both | -Rise | -Fall] [-VERbose]
[{> | >>} *file_pathname*]

Stuck/Transition/Toggle/Iddq Faults Usage:
add_faults {{ **-All** | {***object_expression***…
[-PIN | -INstance | -MODule [-PIN *module_pin_pathname* ...]]}} |
{**-CLOCK_Domains** {**ALL** | ***clock_pathname…***} [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains] } |
{**-CAPture_procedures** {**ALL** | ***capture_procedure_name…***}}}
[-Stuck_at {01 | 0 | 1}] [-VERbose] [{> | >>} *file_pathname*]

Bridge Faults Usage:
add_faults {{**-All** | {***bridge_name***… -NAME} | {***net_pathname***… -SINGle}|
{***instance_name***… -SINGle}} |
{**-CLOCK_Domains** {**ALL** | ***clock_pathname…***} [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains]} |
{**-CAPture_procedures** {**ALL** | ***capture_procedure_name…***}} [{> | >>} *file_pathname*]

UDFM Faults Usage:
add_faults { **-All** | { object_expression... [-INstance] } }
| {**-CLOCK_Domains** {**ALL** | ***clock_pathname…***} [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains] }
{ [-Udfm_type *name*][-CEll *name*] [-MODule *name*] [-FAult *name*] } [-VERbose]

Power-Aware Options (applicable only after you have loaded CPF/UPF power data):
[[-ON_domains] | [-OFf_domains] | [-POWer_domains {*domain_name* …}]]
[-ISolation_cells] [-LEvel_shifters] [-REtention_cells]

Description

Adds faults to the current fault list, discards all patterns in the current test pattern set, and sets all faults to undetected (actual category is UC).

When you enter the Setup mode, all faults from the current fault list are deleted. Furthermore, if you change the fault type, all faults are deleted. The power-aware options add faults based on power domains and/or power features after you have loaded a CPF or UPF file.

You cannot add faults for clock domains, capture procedures, and specific objects or paths within the same command instance. Use a separate command instance for each.

With the fault mode set to “uncollapsed” (the invocation default), all possible faults are added to the list. If you change the fault mode to “collapsed” with the set_fault_mode command, only one instance of any given fault is added, ignoring any equivalent faults.

Note

The add_faults command does not add faults that are protected as a result of a prior “read_faults -protected” or “set_fault_protection on” command to the internal fault list. Nor does it add faults that are equivalent to the protected faults; these faults are added to the internal list of protected faults.

Arguments

- **-All**

  A required switch that adds all faults, depending on the fault model.

  - **Bridge Faults** — Adds all previously loaded bridge entries to the internal fault list. This is the default behavior.
  - **UDFM Faults** — Adds faults for all previously loaded UDFM fault sites to the internal fault list. This is the default behavior.
  - **Non-Bridge Faults** — Adds all faults on all model, netlist primitive, and top module pins. The setting of the set_internal_fault command affects the behavior of this switch. If the set_internal_fault command is set to “off” (the default), the switch only adds faults residing on the boundaries of library cells. If the set_internal_fault command is set to “on”, the -All switch adds faults that reside on the inputs and outputs of gates within library cells. For more information about fault locations, refer to “Fault Locations” in the *Tessent Scan and ATPG User’s Manual*.

- ***name_of_delay_path***

  A required, repeatable string that specifies the names of the delay paths whose faults you want added to the current fault list. The name must correspond to the name of a delay path defined in the path definition file.

- -Both | -Rise | -Fall

  An optional switch that specifies which faults to add for each path already added via the Add Paths command. These switches are used for path delay faults only.

  -Both — Adds both the slow-to-rise and slow-to-fall faults. This is the default.

  -Rise — Adds only the slow-to-rise faults.

  -Fall — Adds only the slow-to-fall faults.

- ***object_expression***

  A required, repeatable string that specifies a list of instances or pins whose faults you want added to the current fault list. Note that in the case of UDFM, you can specify only instances. You can use regular expressions, which may include any number of asterisk (*) and question mark (?) wildcard characters.

Instance pathnames must be ATPG library cell instances. Pin pathnames must be ATPG library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of an ATPG library model, the tool ignores it. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the -Pin or -Instance switch after the *object_expression*.

- -PIN

  An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool will then add faults for all the pins matched.

- -INstance

  An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool will then add faults for all the pins on the instances matched.

- -MODule [-PIN *module_pin_pathname* ...] (Stuck/Transition/Toggle/Iddq only)

  A switch that specifies to interpret the object_expression argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the object_expression argument, and the tool adds the fault for all matching modules or library models.

  When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given object_expression and adds faults for every pin specified in module_pin_pathname list.

- ***bridge_name***

  A required, repeatable string that specifies bridge names whose bridge faults you want added to the current fault list.

- ***net_pathname***

  A required, repeatable string that specifies single net names whose bridge faults you want added to the current fault list.

- ***instance_name***

  A required, repeatable string that specifies instances names whose bridge faults you want added to the current fault list.

- -NAME

  An optional switch that specifies all entered strings are bridge names.

- -SINGle

  An optional switch that specifies all the entered strings are either a single net or instance. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.

  If the string specifies a net, faults are added to the fault list for each bridge entry associated with the net.

If the string specifies an instance that contains a non-dominant net specified in a bridge entry, associated faults are added to the fault list.

- **-CLOCK_Domains** {**ALL** | ***clock_pathname…***}

  A required switch and literal or repeatable string pair that specifies a list of clocks and directs the tool to add only faults that are potentially detectable using any of the specified clocks (or equivalent clocks). For a transition fault to be potentially detectable, it must be detectable when the same clock (one of the specified clocks or an equivalent) is used for launch and capture. Any other type of fault must be detectable when one of the specified clocks or equivalents is used as the capture clock.

  When you use this switch, the tool ignores the constraint values implied in the data path when adding faults in the data path. However, the tool still considers the constraint value for the clock cone tracing to determine the state element clock domain.

  The argument choices are as follows:

  ALL — A literal that specifies all the clocks in the design.

  clock_pathname — A repeatable string that specifies individual clocks.

Note

A fault added using this switch might also be detectable by an unspecified clock.

- -NO_EQUivalent_clocks

  An optional switch that prevents the -Clock_domains switch from adding faults in equivalent clock domains.

- -INCLUDE_INTER_NORACE_clock_domains

  An optional switch used with -Clock_domains to instruct the tool to take user-defined non-race clocks into account when adding faults in the clock domain. You can use this switch in non-setup mode and when the clock restriction is set to be domain_clock.

- **-CAPture_procedures** {**ALL** | ***capture_procedure_name…***}

  A required switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to add faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

  ALL — A literal that specifies all enabled named capture procedures.

  capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

  For information about enabling or disabling named capture procedures, see the set_capture_procedures command description.

- -Stuck_at {01 | 0 | 1}

  An optional switch and literal pair that specifies which stuck-at or transition faults to add to the fault list.

01 — A literal specifying that, for stuck-at faults, the tool add both the “stuck-at-0” and “stuck-at-1” faults; or for transition faults, the tool add both “slow-to-rise” and “slow-to-fall” faults. This is the default.

0 — A literal specifying that, for stuck-at faults, the tool add only the “stuck-at-0” faults; or for transition faults, the tool add only “slow-to-rise” faults.

1 — A literal specifying that, for stuck-at faults, the tool add only the “stuck-at-1” faults; or for transition faults, the tool add only “slow-to-fall” faults.

- -Udfm_type *name*

  A switch and string pair that specifies a UDFM type. Use this switch to add faults associated with a specified UDFM type. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- -CEll *name*

  A switch and string pair that specifies a library cell. Use this switch to add faults associated with a specified library cell. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- -MODule *name* (UDFM only)

  A switch and string pair that specifies a module. Use this switch to add faults associated with a specified module. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- -VERbose

  By default, when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, a summary message similar to the following is output:

  // Note: Adding faults for 330 fault sites.

  When you specify the optional -VERbose switch, the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

  If you use actual instance or pin names instead of wildcards, then this switch has no effect.

  When you specify the -Udfm switch and include the -Verbose option, the tool outputs a message similar to the following:

  // Note: Adding 627224 for 27398 instances

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

- -ON_domains

  An optional switch that adds faults on all power-on domains.

- -OFF_domains

  An optional switch that adds faults on all power-off domains.

- -Power_domains {*domain_name* …}

  An optional switch and repeatable string that adds faults on the specified power domains (*domain_name*).

- -Isolation_cells

  An optional switch that adds faults on all isolation cells.

- -Level_shifters

  An optional switch that adds faults on all level shifters.

- -REtention_cells

  An optional switch that adds faults on all retention cells.

Example 1

The following example adds all faults to the circuit so you can run an ATPG process:

set_system_mode analysis
create_patterns

Example 2

The following example uses a prefix match to add faults only to pins on instances whose pathnames begin with “/u9/u2/LCT_reg”:

add_faults /u9/u2/LCT_reg*

```
=== Found 16 design pins ===
/u9/u2/LCT_reg_0_/A0
/u9/u2/LCT_reg_0_/A1
/u9/u2/LCT_reg_0_/S0
/u9/u2/LCT_reg_0_/Y
/u9/u2/LCT_reg_1_/A0
/u9/u2/LCT_reg_1_/A1
/u9/u2/LCT_reg_1_/S0
/u9/u2/LCT_reg_1_/Y
/u9/u2/LCT_reg_2_/A0
/u9/u2/LCT_reg_2_/A1
/u9/u2/LCT_reg_2_/S0
/u9/u2/LCT_reg_2_/Y
/u9/u2/LCT_reg_3_/A0
/u9/u2/LCT_reg_3_/A1
/u9/u2/LCT_reg_3_/S0
/u9/u2/LCT_reg_3_/Y
```

Example 3

The following example uses the same prefix match as the preceding example, but includes the -Instance switch:

delete_faults -all
add_faults /u9/u2/LCT_reg* -instance

```
=== Found 4 design instances ===
/u9/u2/LCT_reg_0_
/u9/u2/LCT_reg_1_
/u9/u2/LCT_reg_2_
/u9/u2/LCT_reg_3_
```

Notice that when you use the -Instance switch, the command lists the instances whose pins are faulted as a result of the wildcard character rather than listing each individual pin.

Example 4

The following example demonstrates how to wildcard the second level of hierarchy:

add_faults /u9/*/LCT_reg_0_ -instance

```
=== Found 4 design instances ===
/u9/u4/LCT_reg_0_
/u9/u3/LCT_reg_0_
/u9/u2/LCT_reg_0_
/u9/u1/LCT_reg_0_
```

Example 5

The following example combines a wildcard character at the second level of hierarchy with a prefix match:

add_faults /u9/*/LCT_reg* -instance

```
=== Found 32 design instances ===
/u9/u4/LCT_reg_0_
/u9/u4/LCT_reg_1_
/u9/u4/LCT_reg_2_
/u9/u4/LCT_reg_3_
/u9/u4/LCT_reg_4_
/u9/u4/LCT_reg_5_
/u9/u4/LCT_reg_6_
/u9/u4/LCT_reg_7_
/u9/u3/LCT_reg_0_
/u9/u3/LCT_reg_1_
/u9/u3/LCT_reg_2_
...
/u9/u2/LCT_reg_5_
/u9/u2/LCT_reg_6_
/u9/u2/LCT_reg_7_
/u9/u1/LCT_reg_0_
/u9/u1/LCT_reg_1_
/u9/u1/LCT_reg_2_
/u9/u1/LCT_reg_3_
/u9/u1/LCT_reg_4_
/u9/u1/LCT_reg_5_
/u9/u1/LCT_reg_6_
```

```
/u9/u1/LCT_reg_7_
```

Example 6

The following example adds only faults in the power domain named PD1:

```
add_faults -power_domain PD1
```

Example 7

The following example uses a prefix match to add faults to pins on instances whose pathnames begin with “/u9/u2/LCT_reg” plus all level shifters in the design:

```
add_faults /u9/u2/LCT_reg* -level_shifters
```

Example 8

The following example adds *intra_cell_bridges* UDFM fault models associated with all library cells that start with *mux* to the current fault list.

```
add_faults -all -udfm_type intra_cell_bridges -cell mux*
```

Example 9

The following example adds intra_cell_bridges UDFM fault models to the instance my_module1_ins/my_module1_or02. Note, when adding a UDFM fault model, the -instance switch is not used.

```
add_faults my_module1_ins/my_module1_or02 -udfm_type intra_cell_bridges
```

Example 9

The following example adds fault models to every module in the current fault list whose name begins with *adder*.

```
add_faults -all -module adder*
```

Example 10

The following example displays the fault value on the specified gate_pin after the add_faults command is executed:

```
add_nofaults ha1/ddd/q -Pin -Stuck 1
add_nofaults ha1/ddd/clk -Pin -Stuck 0
add_nofaults ha1/ddd/d -Pin -Stuck 01
....
add_faults -all
....

foreach_in_collection i [get_gate_pins ha1/ddd/* ] {
        puts "[get_name_list $i] fault_site: [get_attribute_value_list $i -name fault_site]"

}
```

```
ha1/ddd/clk   fault_site: 1
ha1/ddd/d   fault_site: none
ha1/ddd/q   fault_site: 0
```

add_icl_ports

Context: patterns -ijtag

Mode: setup

Usage

add_icl_ports ***port_objects*** [-type { data_in | data_out}]

Description

Specifies top design ports that will be added as DataInPort or DataOutPort ports in the ICL file generated during ICL extraction.

You must specify the current design with the set_current_design command before issuing this command. Changing the current design will discard all previously specified DataInPort or DataOutPort ICL ports. The tool validates that the ports specified as data_in are input or bidirectional ports, and ports specified as data_out are bidirectional or output ports.

Note

You must load the design (gate-level Verilog or RTL) before you issue the set_current_design command as the tool verifies that the specified ports exist in the portlist. You may also load the top level design as a black-box module.

During ICL extraction, top level ports in the controlling fanin of DataInPort ports of sub-modules will automatically be inferred as DataInPort ports and top level ports in the controlling fanout of DataOutPort ports of sub modules will automatically be inferred as DataOutPort ports. You use this command if you want the top level ICL file to declare DataInPort ports and/or DataOutPort ports even when they don't have any DataInPort or DataOutPort ports in their fanin or fanout. Once a port is identified as a DataInPort in the ICL file, it can then be set using the iWrite command. Once a port is identified as a DataOutPort in the ICL file, it can then be observed using the iRead command. Later on, when the current design is integrated into a higher module, ICL extraction will trace the newly created DataInPort ports and DataOutPort ports and ijtag retargeting can be used to retarget the iWrite and iRead commands to the boundary of the new top module.

Arguments

- ***port_objects***

  A required string that specifies a design port name, a tcl list of design port names or a collection of design ports. An error is generated if the specified ports are not found in the portlist of the design.

- -type { data_in | data_out }

  An optional switch and literal pair that specifies whether the specified ports are labeled as DataInPort ports or DataOutPort ports in the generated ICL module. If the -type option is not specified, the ICL port type will be inferred as DataInPort for input and bidirectional

ports and DataOutPort for output ports. An error is generated if -type data_in is specified for an output port or -type data_out is specified for an input port.

Example

The following example declares an ICL DataInPort port D1, and three ICL DataOutPort ports O1 O2 and O3. The generated ICL module will include “DataInPort D1;”, “DataOutPort O1;”, “DataOutPort O2;” and “DataOutPort O3;” even if no ICL ports traced to or from them in the design.

```
set_current_design top
add_icl_ports D1 -type data_in
add_icl_ports {O1 O2 O3} -type data_out
```

delete_icl_ports

add_icl_scan_interfaces

Context: patterns -ijtag, dft

Mode: setup, insertion (dft context only)

Usage

add_icl_scan_interfaces ***name_list***

Description

Adds the specified scan interfaces to the new ICL top module that will be created during ICL extraction.

You only need to use this command if the top module on which ICL extract is running has more than one ScanInterface. In most cases, even when the top module has more than one ScanInterface, ICL extract is able to infer them correctly from the connections to and from the lower-level ICL modules. Only in complicated cases, the heuristic used by ICL extraction may fail; in this case, you use this command to describe the ScanInterface of the top module and they will be reflected in the generated ICL of the top module.

Every ScanInterface must have a port list, so after using the add_icl_scan_interfaces command, use the set_icl_scan_interface_ports command to set the list of ports for each ScanInterface.

You must set the current design with set_current_design before using the add_icl_scan_interfaces command.

Arguments

- ***name_list***

  A required list that specifies the names of scan interfaces that ICL extraction will create in the new ICL top module.

Example

In the following example, the add_icl_scan_interfaces command will create ScanInterfaces named TAP and Internal in the new ICL top module during ICL extraction. The set_icl_scan_interface_ports command will add the names of the ports to the TAP and Internal ScanInterfaces.

set_current_design tap1

add_icl_scan_interfaces {TAP Internal}

set_icl_scan_interface_ports -name TAP -ports {tck tdi tdo tms trst}

set_icl_scan_interface_ports -name Internal -ports {tdo tdrEn1 fromTdr1 ce se ue}

The resulting ICL model would look like this:

```
Module tap1 {

   TCKPort         tck;
   ScanInPort      tdi;
   ScanOutPort     tdo       {  Source IRMux; }
```

```
    TMSPort         tms;
    TRSTPort        trst;
    ToSelectPort    tdrEn1    {  Source sel1;  }
    ScanInPort      fromTdr1;
    ToCaptureEnPort ce;
    ToShiftEnPort   se;
    ToUpdateEnPort  ue;

    ScanInterface TAP {Port tck; Port tdi; Port tdo; Port tms; Port trst;}
    ScanInterface Internal {Port tdo; Port tdrEn1; Port fromTdr1; Port ce;
Port se; Port ue;}
```

Note

Every ScanInterface must have a port list. After using the add_icl_scan_interfaces command, use the set_icl_scan_interface_ports command to set the list of ports for each ScanInterface.

get_icl_scan_interface_list
get_icl_scan_interface_port_list
set_icl_scan_interface_ports

add_iddq_exceptions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

add_iddq_exceptions ***ZVAL_gate…***

Description

Enables you to specify individual sites where the tool does not apply the Iddq restrictions.

You can achieve maximum quiescence by using the appropriate IDDQ checks, and adding exceptions for as few sites as possible while still obtaining patterns that are not rejected for violation of IDDQ checks during fault simulation.

For more information on IDDQ, refer to "Creating an IDDQ Test Set" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- ***ZVAL_gate…***

  A required repeatable string that declares the gate name or gate identification number of a site for which the tool could report Iddq check violations. (See the set_iddq_checks command for specifics about setting Iddq checks). These sites are always roots of tri-state buses (ZVAL gates at the primitive level).

Note

If a site does not have a unique name, you must provide a gate identification number.

The "report_gates -type zval" command gives a list of all candidates, but typically you only need to use the gate identification numbers reported by the analyze_restrictions command.

Example

The following example adds Iddq restrictions, uses the analyze_restrictions command to locate the sources of violations, then adds an Iddq exception to remove one of them.

set_iddq_checks -int_float
simulate_patterns
analyze_restrictions

```
...
//  Will attempt to locate and report specific -int_float violators.
//  No single bus is constrained to Z (or already Z).  Will analyze
further.
//  The following ZVAL gates cause -int_float to fail by themselves.
//    ZVAL gate /cpu/alu/U2392/ (54417).  ABORTed.
//    ZVAL gate /cpu/alu/U4177/ (63712).  ABORTed.
...
```

add_iddq_exceptions /cpu/alu/U2392/

To use the analyze_restrictions command most effectively, you must have design knowledge; in some cases, design knowledge is required in order to pinpoint the source of the violation.

add_ijtag_logical_connection

Context: patterns -ijtag

Mode: setup

Usage

add_ijtag_logical_connection **-from** *source_pin_or_port_name*
-to *destination_pin_or_port_name*

Description

Creates a new logical connection path through the current design by specifying the source and destination of the logical path.

During ICL connection tracing, logical connections will be followed in preference to the actual connections. When tracing reaches an instance pin with a logical connection, it will follow the logical connection across the design hierarchy. A forward trace will only follow logical connections that start on the pin being traced and then skip to the destination of the logical connection. A backward trace will only follow logical connections that have a destination on the pin being traced and then skip to the source of the logical connection.

See "Example 1" on page 479 for an example of a logical connection .

Use this command with care as it basically bypasses the structural tracing of the circuit and uses an act of faith on the behavior of the specified logical source. If the behavior turns out to be inconsistent with the specified logical sources, you will only detect the issue in simulation. Use this command to model logical sources through blackbox modules or to model a path where the logic is too complex. A circuit that gates TCK with capture and shift enable provides proper capture and shift behavior but would not be properly traceable by ICL extraction. In such a case, using a logical source to allow tracing through the tck gating logic is needed.

The following attributes are used to store the source...destination relationship for the two ends of the logical connection:

Table 7-6. Logical Connection Attributes

Attribute Name	Usage
ijtag_logical_hier_connection_from_src	Associated with the top-level module port or instance pin that is the destination of an hierarchical logical connection. A string list of top level module port names and hierarchical instance pin path names to the source ends of of these logical connections. This attribute is not inherited but does cause the the hierarchical boundary to be preserved.
ijtag_logical_hier_connection_to_dst	Associated with the top-level module port or instance pin that is the source of an hierarchical logical connection. A string list of top level module port names and hierarchical instance pin path names to the destination ends of of these logical connections. This attribute is not inherited but does cause the the hierarchical boundary to be preserved.

The following figure illustrates the usage of these attributes.

Figure 7-5. Logical Connection Attributes

These attributes are available for direct read only introspection by the user, like the other predefined ICL extraction attributes. They will all be cleared when the set_current_design command is executed.

Arguments

- **-from** *source_pin_or_port_name*

  A required switch and value pair that specifies the source point of the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.

- **-to** *destination_pin_or_port_name*

  A required switch and value pair that specifies the destination point of the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.

Example 1

The following example illustrates a logical connection from pin U1/Y to pin U2/A. A forward trace that arrives at pin U1/Y will continue on from pin U2/A. A backward trace that arrives at pin U2/A will continue on from pin U1/Y.

Figure 7-6. Logical Connection Example

At the netlist level all interconnections start at an instance pin or a top level module port and end at an instance pin or top level module port. Establishing a logical connection within the design hierarchy will not alter the way that that design hierarchy is traversed by ICL extraction tracing when that design hierarchy is used as part of a larger design hierarchy, from a different top level module.

Example 2

The add_ijtag_logical_connections command will create logical connection between the pins /i2/in and /i2/out, /i3/in and /i3/out and i4/in and /i4/out. The report_ijtag_logical_connections command will report all logical connections in the current design.

add_ijtag_logical_connection -from /i2/in -to /i2/out

add_ijtag_logical_connection -from /i3/in -to /i3/out

add_ijtag_logical_connection -from /i4/in -to /i4/out

report_ijtag_logical_connections

```
//  IJTAG Logical Connections:
//  From Source  To Destination
//  ===========  ==============
//  /i2/in       /i2/out
//  /i3/in       /i3/out
//  /i4/in       /i4/out
//  /i5/in       /i5/out
```

constraint_switch} |
{[-EQuivalent *reference_pin* [*equivalent_pin*]… [-INvert *inverted_pin*…]]
[***constraint_switch***]}}
[-HOld] [-NO_Z] [-SLow_pad [-CELL *model_name*]]

Context: patterns -ijtag

add_input_constraints
{{[-ALl | *primary_input_pin_name*… | -BIDI_Only | -BIDI_Exclude]
constraint_switch} |
{[-EQuivalent *reference_pin* [*equivalent_pin*]… [-INvert *inverted_pin*…]]
[***constraint_switch***]}}

Description

Constrains primary inputs to specified values.

The add_input_constraints command constrains primary input pins to specified values.

Note

Do not force a constrained pin to a new value in any cycle of a named capture procedure (NCP), even temporarily. To ensure state stability, a constrained pin's state must be kept constant for all cycles of NCPs.

Note

In the patterns -ijtag context, you can constrain all Verilog ports unless the port is also an ICL port. Input constraints on ICL ports are allowed only for ICL ports of type TRSTPort and ClockPort. For more information, see "Constraining Inputs" in the Tessent IJTAG User's Manual.

Arguments

- -ALl

  An optional switch that applies the constraint to all applicable primary input pins except clocks, read controls, and write controls. If -Slow_pad is also specified, the constraint is only applied to primary input pins that can take a Z value. This is the default.

- *primary_input_pin_name*

  An optional, repeatable string that specifies the name of a primary input pin to which to apply the constraint.

- -BIDI_Only

  An optional switch that specifies to apply the constraint to bidirectional pins only.

- -BIDI_Exclude

  An optional switch that specifies to apply the constraint only to primary input pins that are not bidirectional.

- -SCAN_INputs

  An optional switch that specifies to apply the constraint to scan input pins only.

- -EQuivalent *reference_pin* [*equivalent_pin*]…

  An optional switch, string, and repeatable string triplet that specifies for the *primary_input_pin_name*(s) to take on the value of the *reference_pin*. If you optionally specify one or more of the *primary_input_pin_name*(s) as *equivalent_pin*(s), those PI's in the *equivalent_pin* list take on the value of the *reference_pin*.You must list pins you want to be equivalent in value to the reference pin before the -Invert argument when used.

- -INvert *inverted_pin*…

  An optional switch and repeatable string that together with the -Equivalent switch specify for the primary input pins, *inverted_pin*, to take on the inverted value of the *reference_pin*. You must list the pins you want to be inverted in value after the -Invert argument.

- ***constraint_switch*** or *constraint_switch*

  A required or optional switch (depending on the arguments you use with it) that specifies the constant value to which to constrain the primary input pin(s). The choices, from which you can specify only one, are as follows:

  -C0 — Specifies application of the constant 0 to the chosen primary input pin.

  The tools do not use constant 0 constraints to determine tied circuitry. Therefore, faults associated with line holds resulting from these constraints are classified as ATPG_untestable (AU), as opposed to Tied (TI) or Blocked (BL). Use a -C0 constraint if the constraint is valid in test mode, but *not* valid in system mode.

Note

If the constraint is valid in system mode as well, consider using -CT0 instead. Faults associated with tied circuitry resulting from a -CT0 constraint are not classified as ATPG_untestable, thereby improving test coverage compared to using a -C0 constraint. To ensure the improvement in coverage matches reality, however, be sure to use -CT0 only for valid system mode constraints.

-C1 — Specifies application of the constant 1 to the chosen primary input pin.

The tools do not use constant 1 constraints to determine tied circuitry. Therefore, faults associated with line holds resulting from these constraints are classified as ATPG_untestable (AU), as opposed to Tied (TI) or Blocked (BL). Use -C1 if the constraint is valid in test mode, but *not* valid in system mode.

Note

If the constraint is valid in system mode as well, consider using -CT1 instead. Faults associated with tied circuitry resulting from a -CT1 constraint are not classified as ATPG_untestable, thereby improving test coverage compared to using a -C1 constraint. To ensure the improvement in coverage matches reality, however, be sure to use -CT1 only for valid system mode constraints.

-CX — Specifies application of the constant X (unknown) to the chosen primary input pin. The tools do not use the specified primary input pin for control.

-CZ — Specifies application of the constant Z (high-impedance) to the chosen primary input pin. The CZ constraint is only applicable to bidi pin and PI that fans out only to Z consumer gates, such as PO, or bus. For a PI that fans out to non Z consumer gate, when CZ is added the tool will issue a warning message during the flattening process and convert CZ constraint into CX constraint automatically. For example:

```
// Warning: Invalid constant Z pin constraint on pin te5 changed to
// constant X.
```

-CT0 — Specifies application of the constant TIE0. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CT0 pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are *not* included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -C0 pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CT0 instead of a -C0 constraint; but take care that any -CT0 constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

Note

You cannot override a -CT0 value (from a test procedure file for example). If you need this flexibility, use -C0 instead.

-CT1 — Specifies application of the constant TIE1. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CT1 pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are not included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -C1 pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CT1 instead of a -C1 constraint; but take care that any -CT1 constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

Note

You cannot override a -CT1 value (from a test procedure file for example). If you need this flexibility, use -C1 instead.

-CTZ — Specifies application of the constant TIEZ. The ATPG process treats this constraint as if you had added a tied signal.

The tools classify faults associated with tied circuitry resulting from a -CTZ pin constraint as untestable (Tied (TI) or Blocked (BL)). These faults are not included in the calculation of test coverage, so they neither raise nor lower coverage. If instead, the faults were associated with a -CZ pin constraint, the tool would classify them as ATPG_untestable (AU) and they would reduce coverage. Therefore, it is advantageous to use a -CTZ instead of a -CZ constraint; but take care that any -CTZ constraint you apply for test is valid in system mode—to ensure the relative boost in coverage is real.

- -HOld

  An optional switch that, for clock sequential patterns only, holds the constant constraint value at the primary input(s) for all cycles of a clock_sequential or multiple_load pattern. Even if a pattern has multiple loads, the primary input's value cannot change among different load intervals. The hold does not apply to clocks, read controls and write controls. It also does not apply to launch off shift patterns, RAM sequential patterns, or patterns with a clock procedure.

  If the fault type is set to transition and you enter a "set_transition_holdpi On" command, the constraint defined by the add_input_constraints command is overridden by the set_transition_holdpi command; that is, all primary inputs except clocks and read/write controls are going to hold their values even if you have not applied a constraint to a particular primary input. Similar behavior occurs when the fault type is set to path delay and you enter a "set_pathdelay_holdpi On" command.

- -NO_Z

  An optional switch that specifies not to allow a Z value at the specified primary input pin(s) during test generation, even if the pins can support a Z value. During good machine simulation, a pattern is rejected if it assigns a Z value to any primary input that is specified to have no Z value. This switch is invalid with either the -CZ or -CTZ switch.

- -SLow_pad

  An optional switch that specifies to X out the value at a bidirectional pin if the pin is driven from within during test generation.

  -CELL *model_name*

  An optional switch and string pair that together with the -Slow_pad switch specifies the scope of the bidirectional pins to be included as slow pads. Only the bidirectional pins that drive the instances initiated from the specified library cell name are added as slow pads.

Example 1

The following example shows two differential clocks, CLK1 off state 0 and CLK2 off state 1. Since the pins are equivalent, you only need to add the clock to one of the pins.

SETUP> **add_input_constraints -equivalent CLK1 -invert CLK2**

SETUP> **add_clocks 0 CLK1**
// Note: Equivalent pin CLK2 also added to clock list.

Example 2

The following example shows how to add equivalent clocks that are inverted.

SETUP> **add_clocks 0 mode[1] -free_running**

SETUP> **add_clocks 1 mode[2] -free_running**

SETUP> **report_clocks**

```
User-defined Clocks (2):
---------  ------------  --------  -------  ----------------
Off State   Constraints  Internal  Name     Other Properties
---------  ------------  --------  -------  ----------------
     1      Free running     No     mode[2]
     0      Free running     No     mode[1]
```

SETUP> **add_input_constraints -equivalent mode[1] -inv mode[2]**

SETUP> **report_input_constraints**

```
//  Primary Input  Equivalent  C-Type  Hold      No-Z      Slow-Pad
//  -------------  ----------  ------  ----  ------------  --------
//  mode[1]                     NONE    No   Undetermined     No
//                 ~mode[2]     NONE    No   Undetermined     No
```

Related Commands

delete_input_constraints

report_input_constraints

add_lfsr_connections

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

add_lfsr_connections ***pin_pathname lfsr_name position***…

Description

Connects an external pin or an internal pin to a Linear Feedback Shift Register (LFSR).

The add_lfsr_connections command connects a core logic pin to an LFSR. You specify this pin with the *pin_pathname* argument. LFSR bit positions have integer numbers, where 0 indicates the least significant bit position. The tool assumes that the output of the 0 bit position connects to the input of the highest bit position. If you select multiple bits of a Pseudo-Random Pattern Generator (PRPG) for the *position* argument, the tool assumes they are all exclusive-ORed together to create the value for the pin.

If you determine that multiple pin names must connect to a bit position of a Multiple Input Signature Register (MISR), you must issue a separate add_lfsr_connections command for each pin. The tool assumes the pins are all exclusive-ORed together to create the value for the next MISR input. The tool also assumes that the physical placement of the MISR connections is after the tapping points as shown in Figure 7-7.

Figure 7-7. MISR placement

You can use the report_lfsrs command to display all the LFSRs with their current values and tap positions.

Arguments

- ***pin_pathname***

  A required string that specifies the pin pathname (*<instance pathname>/<pinname>*) of the core logic pin that you want to connect to the LFSR specified by *lfsr_name*.

- ***lfsr_name***

  A required string that specifies the name of the LFSR to which you want to connect the *pin_pathname*.

- ***position***

  A required repeatable integer that specifies the bit positions of the *lfsr_name* at whose outputs you want to place connections. A bit position is an integer number, where 0 indicates the least significant bit position. The tool assumes the output of the 0 bit position connects to the input of the highest bit position.

Example

The following example connects an LFSR to a scan-in pin and another LFSR to a scan-out pin:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
add_lfsr_connections scan_in.1 lfsr1 2
add_lfsr_connections scan_out.0 misr1 3
```

Related Commands

add_lfsr_taps
delete_lfsr_connections
report_lfsr_connections

add_lfsr_taps

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

add_lfsr_taps ***lfsr_name position***…

Description

Adds the tap configuration to a Linear Feedback Shift Register (LFSR) or a PRPG of type cellular automata (CA).

The add_lfsr_taps command sets the tap configuration of an LFSR. LFSR bit positions have integer numbers, where 0 indicates the least significant bit position. The tool assumes the output of the 0-bit position connects to the selected tap points and that the 0-bit position cannot itself be a tap point.

If the LFSR is defined as a CA, the tap positions define the position of the self-feedbacks cells (those CA cells defined using rule 150). At least one tap must be defined; otherwise, the consistency check of the PRPG issues an error message.

You can use the report_lfsrs command to display all of the LFSRs with their current values and tap positions. You can change the default setting of the *tap_type* switches by using the set_lfsrs command.

Arguments

- ***lfsr_name***

  A required string that specifies the name of the LFSR on which you want to place the taps.

- ***position***

  A required, repeatable integer that specifies the bit positions of the *lfsr_name* at whose outputs you want to place the taps or, for CAs, the bit positions of the self-feedback cells.

Example 1

The following example places taps on the newly-added LFSRs:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
```

Example 2

The following example defines a 32-bit PRPG with self-feedback cells at positions 3, 7, 12, 15, 23, 25, and 30:

```
add_lfsrs my_prpg prpg 32 FFFFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23 25 30
```

set_lfsrs

add_lfsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

add_lfsrs ***lfsr_name*** {**Prpg** | **Misr**} ***length seed*** [-Both | -Serial | -Parallel]
[-Out | -In | -Ca [-INCrement_step *value*]]

Description

Adds LFSRs for use as PRPGs or MISRs.

The add_lfsrs command defines LFSRs, which the tool uses as PRPGs, to create pseudorandom values for the BIST patterns or as MISRs to compact responses.

You specify the LFSR's shift technique by using one of the following shift_type switches: -Both, -Serial, or -Parallel. You specify the placement of the exclusive-OR taps by using one of the following tap_type switches: -Out or -In; or you specify the type of LFSR as celluar automata using the *tap_type* switch -*Ca*. You can change the default setting of the shift_type and tap_type switches by using the set_lfsrs command.

Arguments

- ***lfsr_name***

  A required string that specifies the name that you want to assign to the LFSR. Note that you cannot use the keyword "all" for this name.

- **Prpg**

  A literal that indicates the LFSR functions as a PRPG.

- **Misr**

  A literal that indicates the LFSR functions as a MISR.

- ***length***

  A required integer, greater than 1, that specifies the number of bits in the LFSR.

- ***seed***

  A required, right-justified, hexadecimal number, greater than 0, that specifies the initial state of the LFSR.

The following lists the shift_type switches of which you can choose only one.

- -Both

  An optional switch specifying that the LFSR shifts both serially and in parallel. This is the default unless you change it with the set_lfsrs command.

- -Serial

  An optional switch specifying that the LFSR shifts serially the number of times equal to the length of the longest scan chain for each scan pattern.

- -Parallel

  An optional switch specifying that the LFSR parallel shifts once for each scan pattern.

The following lists the three tap_type switches of which you can only choose one.

- -Out

  An optional switch specifying that the exclusive-OR taps reside outside the register path. This is the default unless you change it with the set_lfsrs command.

- -In

  An optional switch specifying that the exclusive-OR taps reside in the register path.

- -CA

  An optional switch specifying that the PRPG is of type *cellular automata*. This switch is only valid if the LFSR type is specified as *Prpg*.

- -INCrement_step *value*

  An optional switch that specifies the number of times the PRPG is advanced for each shift cycle. The *value* argument is a required integer.

Example 1

The following example defines an LFSR to be a PRPG and another LFSR to be a MISR:

```
add_lfsrs lfsr1 prpg 5 10 -serial -in
add_lfsrs misr1 misr 5 15 -both -out
add_lfsr_taps lfsr1 1 3
add_lfsr_taps misr1 1 2
```

Example 2

The following example defines an LFSR to be a PRPG without a phaseshifter:

```
add_lfsrs my_prpg prpg 24 FFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23
add_lfsrs connection scanin_1 my_prpg 0
add_lfsrs connection scanin_2 my_prpg 1
...
add_lfsrs connection scanin_24 my_prpg 23
```

Example 3

The following example defines an LFSR to be a PRPG with a phaseshifter:

```
add_lfsrs my_prpg prpg 24 FFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23
add_lfsr_connections scanin_1 my_prpg 0 3 5
add_lfsr_connections scanin_2 my_prpg 1 7 11
...
add_lfsr_connections scanin_24 my_prpg 9 15 23
```

Example 4

The following example defines an LFSR to be a PRPG and specifies to advance the PRPG eight times for each shift cycle.

```
add_lfsrs my_prpg prpg 24 FFFFFF -CA -inc 8
add_lfsr_taps my_prpg 3 7 12 15 23
add_lfsrs connection scanin_1 my_prpg 0
add_lfsrs connection scanin_2 my_prpg 1
...
add_lfsrs connection scanin_24 my_prpg 23
```

delete_lfsrs
report_lfsrs
set_lfsrs
set_lfsr_seed

add_lists

Context: dft -edt, patterns -scan

Mode: analysis

Usage

add_lists ***pin_pathname***...

Description

Adds pins to the list of pins on which to report.

In “dft -edt” context, you cannot report values on gates in the EDT logic with this command because values inside the EDT logic are not always accurate.

Tip: This command is a useful debugging aid, as it provides a way to check the values simulated for specific output pins of cells within the design.

To list all the pins on which the tool will currently report during simulation, use the report_lists command. To turn off reporting of a pin’s simulation values, use the delete_lists command. To direct the tool to write the pins’ simulation values to a file instead of displaying them onscreen, use the set_list_file command.

When switching to Setup mode, the tool discards all pins from the report list.

Arguments

- ***pin_pathname***

  A required, repeatable string that specifies the output pins on which to report during good and/or faulty machine simulation.

Example

The following example writes to the file, *pinlist_goodsim.txt*, the values simulated for two output pins during simulation of an external pattern source:

```
set_system_mode analysis
read_patterns pattern1
add_lists /i_1006/o /i_102/o
set_list_file pinlist_goodsim.txt -replace
simulate_patterns
```

The following shows the format of the resulting list file: the first column lists the pattern index of each pattern simulated, the second column shows the value simulated on each monitored pin for each pattern. Note that the pattern index refers to the simulated parallel patterns rather than the effective patterns that will be stored after ATPG.

```
//        /i_1006/o
//        |/i_102/o
//        ||
//        ||
//----------
```

```
//      0  11
//      1  10
//      2  00
//      3  10
//      4  01
//      5  01
...
```

Notice that in analysis system mode, the report shows the good value of the pin. The tools also shows the values at each test pattern.

The following is example list file content for the same two pins when simulated in the analysis system mode:

```
//        /i_1006/o
//        |/i_102/o
//        ||
//        ||
//----------
//      0  11
//      0  0- { /i_1006/o@0 }
//      1  10
//      1  0- { /i_1006/o@0 }
//      2  00
//      2  1- { /i_1006/o@1 }
//      3  10
//      3  0- { /i_1006/o@0 }
//      4  01
//      4  1- { /i_1006/o@1 }
//      5  01
//      5  1- { /i_1006/o@1 }
...
```

The report now includes two lines of information for each pattern simulated. The first line shows the good machine value of each pin as before. The second line shows the faulty value of each pin if different from the good value (a “-” indicates the faulty value was the same as the good value). Inside the “{}” is the fault site and its faulty machine stuck-at value the tool simulated to produce the faulty machine results.

set_list_file

add_misrs

Context: patterns -scan

Mode: setup, analysis

Usage

add_misrs ***misr_name*** **-size** ***int*** [-seed ***hex***] [-taps ***index***…]

Description

Specifies the MISR structure and initial seed.

This command is used with the hybrid TK/LBIST flow—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

This command is included in the LogicBIST fault simulation dofile to describe the MISR logic synthesized.

Arguments

- ***misr_name***

  A required string that specifies the name of the MISR. The ***misr_name*** is subsequently used by the tool for referring to this MISR for specifying connections from scan chains, and in reporting.

- **-size** ***integer***

  A required switch and integer that specifies size of the MISR.

- -seed ***hexadecimal***

  An optional switch and hexadecimal number pair that specifies the initial seed. Use this command if you intend on performing fault simulation with a different starting MISR seed.

- -taps ***index***

  An optional switch and repeatable integers that specifies the tap points for the MISR feedback network. The tap index starts from 1 to be consistent with the decompressor used as a PRPG in the LogicBIST mode and associated decompressor commands.

Example

This example shows the add_misrs command in context patterns -scan, mode setup. This example adds a 24-bit MISR named "misr" with initial seed of all 0-s:

```
add_misrs misr -size 24 -seed 000000 -taps 21 22 24
```

Related Commands

delete_misrs

report_misrs

report_misr_connections

set_misr_connections

add_nofaults

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

add_nofaults {{ ***modulename*** ... **-Module** [-PIN *module_pin_pathname* ...] | ***object_expression*** ... [-PIN | -Instance]} [-Stuck_at {01 | 0 | 1}] [-Keep_boundary]} | -Wire [-VERBose] [(> | >>) *file_pathname*]

Description

Places nofault settings either on pin pathnames, pin names of specified instances, or modules.

By specifying pathnames of pins, instances, or modules while in Setup mode, the add_nofaults command places a nofault setting either on the specific pins or on boundary and internal pins of the instances or modules. All added nofault pin pathnames are in the user class.

Note

All switches except -Wire are valid only before flattening. The -Wire switch is valid only after flattening.

The -Stuck_at switch applies to either stuck-at faults or transition faults. For the latter, you specify 0 for “slow-to-rise” and 1 for “slow-to-fall” transition faults. If you do not specify a value, then the tool places a nofault setting on both stuck-at (transition) values. If you add faults with the add_faults command after you issue the add_nofaults command, the specified pin pathnames or boundary and internal pins of instances or modules cannot be sites for those added faults.

Note

When you add nofault settings, the tool deletes the flattened simulation model if it exists. This removes information you added after model flattening, such as ATPG functions. To avoid losing this information or having to wait for the tool to flatten the design again, add nofault settings prior to model flattening.

Arguments

- ***modulename***

  A repeatable string that specifies the name of a module to which you want to assign nofault settings. You must include the -Module switch when you specify a module name.

- **-Module** [-PIN *module_pin_pathname* ...]

  A switch that specifies to interpret the ***modulename*** argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the ***modulename*** argument, and the tool adds the nofault for all matching modules or library models.

When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given module name and adds nofaults for every pin specified in module_pin_pathname list.

- ***object_expression***

  A string representing a list of pathnames of instances or pins for which you want to assign nofault settings. You can use regular expressions, which may include any number of asterisk (*) and question mark (?) wildcard characters.

  Pin pathnames must be ATPG library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of an ATPG library model, the tool ignores it. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the -Pin or -Instance switch after the *object_expression*.

- -PIN

  An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool will then assign nofault settings to all the pins matched.

- -Instance

  An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool will then assign nofault settings to all boundary and internal pins of the instances matched (unless you use the -Keep_boundary switch).

- -Stuck_at <u>01</u> | 0 | 1

  An optional switch and literal pair that specifies to which stuck-at or transition values you want to assign a nofault setting. The choices are as follows:

  <u>01</u> — A literal that specifies to place a nofault setting on both the “stuck-at-0” and “stuck-at-1” faults for stuck-at faults; or on both the “slow-to-rise” and “slow-to-fall” faults for transition faults. This is the default.

  0 — A literal that specifies to place a nofault setting on only the “stuck-at-0” faults for stuck-at faults; or on only the “slow-to-rise” faults for transition faults.

  1 — A literal that specifies to place a nofault setting on only the “stuck-at-1” faults for stuck-at faults; or on only the “slow-to-fall” faults for transition faults.

- -Keep_boundary

  An optional switch that specifies to apply nofault settings to the inside of the specified instance/module, but allow faults at the boundary pins of these instances/modules. This option does not apply to nofaults on pin pathnames.

- -Wire

  A switch that specifies for the tool to no-fault a cone of logic fanning out from a stem forward into a single wire gate. The tool no-faults the entire cone of logic between the stem

and the wire gate, but not the stem or the output of the wire gate. There must be no other fanout from this cone of logic. This switch is valid only after flattening.

Note

This switch affects all qualifying logic cones.

- -VERbose

  By default when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, the tool outputs a summary message similar to the following:

  // Note: Adding nofaults for 330 fault sites.

  When you specify the optional -VERbose switch, then the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

  If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

The following example defines nofault settings for all the pins in a particular instance, so when you add all faults to the circuit for an ATPG run, the tool will not place faults on the pins of that instance:

```
add_nofaults i_1006 -instance
set_system_mode analysis
create_patterns
```

Example 2

The following example places nofault settings on all the design pins within all instances of wired cone logic, adds all faults to the circuit, and performs an ATPG run so that Tessent FastScan and Tessent TestKompress place nofaults on the wired cone logic pins:

```
set_system_mode analysis
add_nofaults -wire
create_patterns
```

Related Commands

add_faults

add_nonscan_instances

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

add_nonscan_instances { ***pathname...*** **|** ***instance_expression*** [-INStance | -Control_signal | -Module]} | -All

Description

Marks specific sequential elements for exclusion from the scan insertion process.

The add_nonscan_instances command causes the tool to ignore the specified instances, instances controlled by the specified control signals, all instances within the specified module, or all previously-identified scan instances when you execute the scan identification process with the insert_test_logic command.

Also, the tool will not perform the scannability rule checks on non-scan instances.

If you want to flag all instances of a certain library model as non-scan, you can use the add_nonscan_models command as a shortcut.

When adding non-scan instances with control signals, the tool adds all scannable instances controlled by the control signals to the non-scan instance list. Control pins can be any clock, set, or reset signal (primary input) that controls the contents of sequential instances. You can use the report_control_signals command to see the pins that control the sequential instances in the design.

If TIE0 and TIE1 non-scan cells are scannable, they are considered for scan. However, if these cells are used to hold off sets and resets of other cells so that another cell can be scannable, you must use this command to make them non-scan.

Arguments

- ***pathname***

  A required repeatable string that specifies the pathnames of the sequential instance or control signals (that control instances) which you want the tool to ignore. If the instance is hierarchical, then all instances beneath it are also flagged as non-scan.

- ***instance_expression***

  A string representing a list of instances within the design. The string instance_expression is defined as:

  { string | string * } ...

  The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. You can use a pathname expression to select several instances and the tool

will then add_nonscan_instances for all the pins on those instances; but if the expression specifies a location below the instance level of an ATPG library model, the tool will issue an error message.

- -INStance | -Control_signal | -Module

  An optional switch that specifies whether the pathnames are instances, pins (control signals), or modules. An example Verilog module is “module clkgen (clk, clk_out, …)” where clkgen is the module name. You can only use the -Control_signal option in analysis mode. The default is -Instance.

- -All

  An optional switch that marks every scan cell in the design as a non-scan cell. When you issue the command with the -All switch, the tool completely clears the list of targeted cells, and you can then manually select an arbitrary subset of target cells using the add_scan_instances command.

Example 1

The following example specifies that the tool ignore the sequential i_1006 instance when identifying and inserting the required scan circuitry:

```
add_nonscan_instances i_1006
```

Example 2

The following example clears all previously identified scan cells and then adds two instances to the list of scan cells to be stitched:

```
add_nonscan_instances -all
add_scan_instances i_1006 i_1007
insert_test_logic
```

Related Commands

add_nonscan_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

add_nonscan_models ***model_name***…

Description

Instructs the tool to ignore all instances of the specified sequential DFT library model when identifying and inserting the required scan elements and test logic into the design.

The add_nonscan_models command causes the tool to ignore the instances of the specified models, when you execute the scan identification process and scan insertion process with the insert_test_logic command.

The tool does not check the scannability on the instances instantiated from the added non-scan models, unless you specify checking using the set_lockup_cell command.

If you want to flag individual instances as non-scan, you can use the add_nonscan_instances command.

Arguments

- ***model_name***

  A required repeatable string that specifies the model names that you want the tool to ignore. You must enter the model names as they appear in the DFT library.

Examples

The following example specifies that the tool should not substitute any of the instances of the DFT library model named d_flip_flop with the equivalent scan replacement DFT library model.

```
add_nonscan_models d_flip_flop
```

Related Commands

add_norace_clocks

Context: dft -edt, patterns -scan

Mode: analysis

Usage

add_norace_clocks **-All** | ***clock_pin_name…*** | ***gate_id#…***

Description

Defines one or more non-interacting clocks.

The add_norace_clocks command defines the specified clocks as non-interacting. This gives you a way to override the tool's conservative algorithm for determining non-interacting clocks when you know with certainty that some clocks in your design are non-interacting. By specifying non-interacting clocks explicitly, you can often reduce generated test set size and improve test coverage.

Note

Simulation mismatch errors are likely if you erroneously define as non-interacting, clocks that actually do interact.

The tool includes all the clocks you list in one add_norace_clocks command in the same clock domain. A clock cannot be included in more than one user-defined clock domain, however, so once you define a clock as non-interacting, you cannot add another definition for it until you delete the existing definition using the delete_norace_clocks command. All clocks in the same clock domain may be turned on simultaneously by ATPG.

Arguments

- **-All**

  A switch that specifies all defined clocks.

- ***clock_pin_name…***

  A repeatable string that specifies the name of a defined clock pin.

- ***gate_id#…***

  A repeatable positive integer that specifies the gate identification number of a defined clock pin.

Example

The following example creates a user-defined clock domain for clocks "clk1" and "clk2". The example then tries to include clk1 in another user-defined clock domain. A clock can only belong to one user-defined clock domain, however, so the tool issues an error message. The example follows that with a new, valid definition, then displays the current user-defined clock

domains. Notice the user-defined clock domain does not alter the clock domains the tool determined from its own analysis. The latter are displayed by “report_clock_domains”.

set_system_mode analysis
add_norace_clocks clk1 clk2
add_norace_clocks clk1 clk5

```
// Error: Clock clk1 is already in a user-defined clock domain
```

add_norace_clocks clk3 clk4 clk5
report_norace_clocks

```
// User clock domain 1 : /clk1 /clk2
// User clock domain 2 : /clk3 /clk4 /clk5
```

report_clock_domains

```
// Clock name   Domain
// --------------------
// /clk1 (2)         1
// /clk2 (10)        2
// /clk3 (18)        3
// /clk4 (44)        4
// /clk5 (51)        5
```

add_notest_points

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

add_notest_points {***pin_pathname***… | ***instance_pathname***… | ***instance_expression***} | **-Path** ***filename***

Description

Adds circuit points to the list for exclusion from testability insertion.

The add_notest_points command excludes the specified cell output pins, excludes specified D input scan cells, excludes all output pins on the specified instance, or excludes delay paths from use as controllability and observability insertion points. If the selected pin is already a control or observe point, an error occurs when you issue this command.

If you specify a path file that contains delay paths, the tool marks each gate in the path; consequently, the tool adds no test points to the output of that gate. This prevents control and observation points from being added to a critical path and thus prevents increasing the load on any of these gates in that path. The format of the file is the same as the file loaded with the read_fault_sites command. For more information on the format, refer to "The Path Definition File" in the *Tessent Scan and ATPG User's Manual*.

The report_notest_points command displays all the pins in this list or can list the defined critical paths.

Arguments

- ***pin_pathname***

  A required, repeatable string that lists the output pins that you do not want to use for insertion of controllability and observability.

- ***instance_pathname***

  A repeatable string that lists the instances whose output pins you do not want to use for controllability and observability insertion. All output pins within that (hierarchical) instance are added to the list of pins that should be excluded from consideration.

- ***instance_expression***

  A string representing a list of instances within the design. The string *instance_expression* is defined as:

  { string | string * } ...

  The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. You can use a pathname expression to select several instances and the tool

will then add_notest_points for all the pins on those instances; but if the expression specifies a location below the instance level of an ATPG library model, the tool will issue an error message.

- **-Path *filename***

  A switch and filename pair that specifies the pathname to a file that contains critical path information. For more information on the format of the file, refer to "The Path Definition File" in the *Tessent Scan and ATPG User's Manual*.

Example

The following example specifies output pins that the tool cannot use for testability insertion:

```
add_notest_points i_1006/o i_1008/o i_1009/o
```

Related Commands

delete_notest_points
report_notest_points
set_test_point_insertion_options

add_observe_points

Context: dft -test_points

Mode: setup, analysis

Usage

add_observe_points **-location** ***pin/port_spec***
[-scan_cell_clock ***pin/port_spec***]
[-enable ***pin/port_spec***]

Description

Specifies user-defined observe points during test point insertion.

Arguments

- **-location** ***pin/port_spec***

  A required string that specifies the pathname to the observe point location where ***pin/port_spec*** can be the name of a pin/port, a Tcl list of pins/ports, or a collection of pin/port objects.

- -scan_cell_clock ***pin/port_spec***

  An optional switch and string pair that specifies the path name of the clock signal used to clock the observe point. This can be a collection or list, but should have only one element.

- -enable ***pin/port_spec***

  An optional switch and string pair that specifies the path name of an existing net used to enable/disable the observe point. This can be a collection or list, but should have only one element.

  If you want to specify the default enable signal for the automatically identified observe points instead of manually adding each enable signal, use the set_test_point_insertion_options command as follows:

  set_test_point_insertion_options -observe_points_enable

Example 1

The following example adds two observe points, and specifies the new scan cell model used to observe the inserted test points:

add_observe_points -location ss1/ix348/Z

add_observe_points -location ss1/ix302/Z

Example 2

The following example specifies the path names of existing nets that are to be used to enable/disable the control points and observe points respectively. Then it adds a control point and an observe point, and proceeds to insert the test points into the netlist:

```
set_test_point_insertion_options -control_point_enable cp_enable \
        -observe_point_enable op_enable

add_control_points -location jtc/i1216/OUT -type and

add_observe_points -location jtc/i1645/OUT

...

set_system_mode analysis

...

insert_test_logic
```

add_output_masks

Context: dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

add_output_masks ***primary_output***… | **-All**

For dft -scan

add_output_masks {***primary_output***… | **-All**} [-Nohold | -Hold {0 | 1}]

Description

patterns -scan Details

Ignores any fault effects that propagate to the primary output pins you name.

The tool uses primary output pins as the observe points during the fault detection process. When you mask a primary output pin, you inform the tool to mark that pin as an invalid observation point during the fault detection process. This command allows you the ability to flag primary output pins that do not have strobe capability. The tool classifies the faults whose effects only propagate to that observation point as ATPG_untestable (AU).

dft -scan Details

The tool uses primary output pins as the observe points during the scan identification process. When you mask a primary output pin, you inform the tool to mark that pin as an invalid observation point during the identification process.

There are specific design practices that mask specific primary output pins in order to group the sequential elements associated with those primary outputs (for example, if you are using wrapper chains). For more information on wrapper chains, refer to "Understanding Wrapper Chains" in the *Tessent Scan and ATPG User's Manual*.

You can set a default mask for all output and bidirectional pins using the set_output_masks command. You can add a hold value to a default mask with the add_output_masks command, or remove a hold value using the delete_output_masks command. To turn off the default masks for all output pins, you must use the set_output_masks command with the Off literal.

Arguments

- ***primary_output***

  A repeatable string that specifies the name of the primary output pin you want to mask.

- **-All**

  A switch that specifies to mask all primary output pins.

- -Nohold **(dft -scan)**

  An optional switch that allows any state value on the specified primary output pin. This is the default.

- -Hold 0 | 1 **(dft -scan)**

  An optional switch and literal pair that specifies the state to maintain on the primary output pin. If you use this switch, you can explicitly specify that the output pin is driving the inactive value. The choices for the hold literal value are as follows:

  0 — Maintains a low logic state on the primary output pin.

  1 — Maintains a high logic state on the primary output pin.

Example 1

The following example specifies the primary output pins that will not have the strobe capability on the hardware tester:

```
add_output_masks qb1 qb2 qb3
```

Example 2

The following dft -scan example specifies the primary output pins that the add_output_masks command associates with the wrapper cells.

```
add_output_masks out1 out2 out3
```

When you issue the analyze_wrapper_cells command later in the session, the toolidentifies all the sequential elements that are observable only through the masked primary output pin. Then, when you issue the insert_test_logic command, the tool stitches all those scan cells it previously identified as being wrapper cells into one wrapper chain.

add_primary_inputs

Context: all_contexts

Mode: setup

Usage

add_primary_inputs ***net_pathname***... [-internal] [-name *user_name*]

Description

Adds a primary input (PI) to the specified nets or pins.

This command also designates them as user-class PIs rather than system-class PIs described in the original netlist. Use the -internal switch to disconnect the original drivers of the net, so that the added PI becomes the only driver of the net or pin; otherwise, the net is treated as a wired net if there are other drivers besides the newly added PI. Use the -name switch to specify a list of internal pin pathnames to connect to a single, new primary input pin. You can display the user-class, system-class, or full-class PIs by using the report_primary_inputs command.

Arguments

- ***net_pathname***

  A required, repeatable string that specifies the pathname of a net or pin to which you want to add a primary input. If the -internal switch is used, net_pathname lists internal net pathnames. If both the -internal and -name switches are used, net_pathname lists internal net or pin pathnames to merge into a single, new primary input pin. The net_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- -internal

  An optional switch that specifies net_pathname is an internal net or pin. This switch disconnects the original drivers of the net or pin, making the added primary input the only driver of the net or pin. These primary inputs are not added to the top-level interface when saving patterns. Use this switch to define internal control signals that originate from internal circuitry.

Note

The tool does not fault PIs created using the -internal switch. This allows interchange of fault lists between runs of the tool across different modes where you may have used different cut points.

Note

When you use the write_patterns -Mode_internal switch when saving serial or parallel simulation patterns, the test bench still forces the internal nodes on net_pathname even though the corresponding PIs are not included in the top-level interface. When you save the patterns using the -Mode_external switch, the test bench will *not* force those internal nodes. In this case, unless the circuit generates values on the internal nodes corresponding to what ATPG assumed was forced on the corresponding PIs, you may get simulation mismatches.

- -name *user_name*

  An optional switch and string pair that specifies the name for a new primary input pin name that will drive all the internal pins specified with the net_pathname argument.

Example 1

The following example adds two new primary inputs to the circuit and places them in the user class of primary inputs:

add_primary_inputs indata2 indata4

Example 2

The following example adds a PI to the net originally driven by the output of a NAND gate, disconnecting the output of the NAND from the net. This happens within the tool only; the tool does not modify the original source netlist. The example then reports on the new PI and the original driver of the net. The example begins in setup mode. Notice that the tool reassigns gate IDs in the modified internal netlist.

set_gate_level primitive
create_flat_model
report_gates /ix157/Y

```
//  /ix157 (94)  NAND
//      A0     I  25-/reg_0_/Q
//      A1     I  33-/reg_1_/Q
//      Y      O  142-/d_2_mult_0_/A1
```

add_primary_inputs -internal /d_2_mult_0_/A1

```
//  Warning: Flattened model deleted.
//  Warning: Primary input is added at net '/nx16'
```

report_primary_inputs /nx16

```
USER:  /nx16 CUT
```

set_system_mode analysis
report_gates /nx16

```
//  /nx16 (15)  PI
//      nx16  O  /d_2_mult_0_/A1
//
//  User-added pin driven by "/ix157/Y" (95) in the source netlist.
//
```

report_gates /ix157/Y

```
//  /ix157 (95)  NAND
//      A0     I  26-/reg_0_/Q
//      A1     I  34-/reg_1_/Q
//      Y      O
//
//  Gate drives user-added pin "/nx16" (15) in the source netlist.
//
```

Example 3

The following example connects internal nets “xyz/abc/pina xyz/def/pina xyz/ghi/pina” to a single, new primary input and disconnects the original drivers of the nets, making the added primary input the only driver of the nets. The name of the new primary input pin is “group_pi”.

add_primary_inputs -internal xyz/abc/pina xyz/def/pina xyz/ghi/pina -name group_pi

add_primary_outputs

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -retargeting, patterns -scan_diagnosis

Mode: setup

Usage

add_primary_outputs ***net_pathname***... [-internal] [-name *user_name*]

For dft -scan and dft -test_points

add_primary_outputs ***net_pathname***… [-internal] [-name *user_name*]

Description

Adds primary outputs to the specified net.

The add_primary_outputs command adds an additional primary output to each specified net or pin. Once added, the tool defines them as user-class primary outputs. The tool defines the primary outputs described in the original netlist as system class primary outputs. You can display the user class, system class, or full classes of primary outputs using the report_primary_outputs command.

Arguments

- ***net_pathname***

  A required, repeatable string that specifies the net or pin to which you want to add primary outputs. The net_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- -internal

  An optional switch that specifies net_pathname is an internal net or pin that is driven by the driver of the net_pathname. These primary outputs are not added to the top-level interface when saving mode_external patterns, such as STIL and WGL.

- -name *user_name*

  An optional switch and string pair that specifies the name for a new primary input pin name that will drive all the internal pins specified with the net_pathname argument.

Note

The tool does not fault POs created using the -internal switch. This allows interchange of fault lists between runs of the tool across different modes where you may have used different cut points.

Example

The following example adds a new primary output to the circuit and places it in the user class of primary outputs:

```
add_primary_outputs outdata1
```

Related Commands

add_primary_inputs
delete_primary_outputs
report_primary_outputs

add_processors

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion (dft -edt context only)

Usage

add_processors {***hostname***[:{*cpus* | MAXcpu}]}…

Description

Enables the tool to run multiple processes in parallel on multiple machines to reduce runtime.

The add_processors command enables the tool to use multiple processors simultaneously on specified host machines when executing multiprocessing commands for ATPG or fault simulation. For more information, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual.*

Running multiple processes in parallel can sometimes reduce runtime significantly, especially for large designs. Be sure to load your design in the tool before using the add_processors command. This allows the tool to more accurately estimate memory requirements for the added processors.

Without access to multiple processors, the tool executes as a single master process. When you make additional processors available with the add_processors command, there will still be a single master process, but the tool starts up additional slave processes for parallel execution and coordinates communication between processes.

During ATPG and fault simulation, the tool can optionally use multiprocessing when executing the following commands:

- compress_patterns (fault simulation)
- create_patterns (ATPG)
- identify_redundant_faults (ATPG)
- order_patterns (fault simulation)
- simulate_patterns (fault simulation)

All multiprocessing commands alert you with a message when the design is being sent to slave processors. This message may not appear after subsequent commands if the other processors have already received the design and you have issued no commands in the interim that would affect the information the other processors received. There is currently a limit of 1024 processors per add_processors command.

Tip: To stop the command from waiting any longer for requested slave processes not yet received, and proceed with those it has, use the Control-C key sequence.

Note

IPv4 address support differs slightly by platform due to differences in the underlying system call implementations. These differences may be machine dependent due to dynamic linking with libraries resident on the host computer.

Arguments

- ***hostname***

  A required, repeatable string or literal that specifies a host machine or job scheduler that the tool can use for slave processes.

  The hostname choices are as follows:

  machine_name — A string that specifies a host machine by its network name.

  LOCALHOST — A literal that specifies to use the machine you invoked the tool on as the host machine.

  IPaddress — A string that specifies a host machine by its IP address.

  LSF — A literal that specifies to use available Load Sharing Function (LSF) host machines.

  SGE — A literal that specifies to use available Sun Grid Engine (SGE) host machines.

  GENERIC — A literal that specifies to use a host machine as determined by a custom job scheduler. This option requires that you first issue a set_multiprocessing_options command with the generic_scheduler argument to inform the tool how to launch the custom job scheduler.

Note

The use of job schedulers requires certain environment prerequisites to be satisfied before you invoke the tool. See "Multiprocessing Requirements" in the *Tessent Scan and ATPG User's Manual* for more information.

- :{*cpus* | MAXcpu}

  A colon (:) followed by a positive integer or the MAXcpu keyword with which you can optionally specify the number of processes on the specified host machine or job scheduler to use as slave processes. You can specify up to 32 processes per host. If you specify 0 processes, the tool issues a warning.

  If you specify a positive integer, the tool uses that number of processes.

  If using a job scheduler, the tool uses as many processes as the scheduler provides in the time allotted. The time allotted is determined by the setting of the scheduler_timeout variable, which you can change using the set_multiprocessing_options command.

  If you specify the Maxcpu literal, the tool automatically determines the number of processes the host can accommodate (less one if the host must also run the master process) and use up to that number of processes as slave processes. The invocation default for SGE, LSF and generic is four processes; for the others it is one.

Note

The Maxcpu literal does not apply to grid scheduling or generic scheduling. The tool's Maxcpu calculations are based on currently running processes without considering other slave process specifications on the same command line. If, for example, you use the Maxcpu literal twice in the same command for a given host, the number of slave processes on that machine could exceed the number of available processors.

Example 1

The following example adds processors to the master host, which increases the thread count instead of adding additional slaves:

> **add_processors localhost:4 ;** # adds 4 threads to the master process for a total thread count of 5

```
//   Adding 4 threads to birdeye (master)
// Master with 5 threads running.
```

> **report_processors**

```
//  hosts             threads   arch      CPU(s)    %idle   free RAM  process size
//  ----------------  -------  ------  -----------  -----  ---------  ------------
//  birdeye (master)        5  x86-64  8 x 2.9 GHz    89%  113.91 MB     232.56 MB
//  master with 5 threads running.
```

Example 2

The following example starts a distributed slave process on the host "odin" that runs with 4 total threads. The add_processors command can start only one process per slave host, and create additional processors (to master or slave) as additional threads.

> **add_processors odin:4**

```
//    Adding 4 threads to odin (new slave)
//  Master with 1 thread and 1 slave with 4 threads running (5 total threads).
```

add_read_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -retargeting, patterns -scan_diagnosis

Mode: setup

Usage

add_read_controls **0** | **1** ***primary_input_pin***...

Description

Adds an off-state value to specified RAM read control lines.

The add_read_controls command defines the circuit read control lines and assigns their off-state values. The off-state value of the pins that you specify must be sufficient to keep the RAM outputs stable. You cannot use clocks, constrained pins, or equivalent pins as read control lines.

Note: The tool automatically adds a read control to the clock list during flattening if the flattening process reaches the clock pin of an edge-triggered RAM. In this case, you must ensure that your timeplate includes the waveform for the newly defined clock.

Arguments

- **0**

  A literal that specifies 0 as the off-state value for the RAM read control lines.

- **1**

  A literal that specifies 1 as the off-state value for the RAM read control lines.

- ***primary_input_pin***

  A required, repeatable string that lists the primary input pins you want to designate as RAM read control lines, and to which you are assigning the given off-state value.

Example

The following example assigns an off-state value of 0 to two read control lines, r1 and r2:

```
add_read_controls 0 r1 r2
set_system_mode analysis
create_patterns
```

Related Commands

add_register_value

Context: all contexts

Mode: setup

Usage

add_register_value ***value_name***
{[*value_string* [-Dynamic] [-Radix {Binary | Decimal | Octal | Hexadecimal}]
{-Width [*integer*]}
| {-Pattern_count { SCan_test | CHain_test | ALl }} }
[-LSB_shifted_first] [-INput_pin_inversion] [-OUtput_pin_inversion]

Description

Creates a static or dynamic variable by allowing you to specify a register identifier, ***value_name***, and, optionally, the state string, ***value_string***.

When you specify a value_string, the variable is static by default unless you use the -Dynamic switch.

See "Serial Register Load and Unload for LogicBIST and ATPG" in the *Tessent Shell User's Manual* for complete information.

Arguments

- ***value_name***

  A required string that specifies register value variable. The variable holds a value to load into the register. The register value variable is used in the procedure file to load the value into a register through the data input pin.

- *value_string*

  An optional state string whose default radix is binary. When you specify a value_string, the variable is static by default unless you use the -Dynamic switch. Note that you aren't allowed to specify a value_string when you use the -Pattern_count switch.

- -Dynamic

  An optional switch that forces the variable to be dynamic when you provide an optional value_string. By default, when you provide a value_string, the variable is static.

- -Radix {**Binary** | Decimal | Octal | Hexadecimal}

  An optional switch and literal that specifies the radix of the value_string. If you specify the -Radix switch, then you must specify the register width using the -Width switch.

- -Width *integer*

  A switch and integer pair that specifies the register width. When defining a dynamic variable, you must use this switch. If you do not know the actual width value until after test generation completes, then use the -Width switch without ***integer***, and specify the width using the set_register_value command.

The maximum width of a register value is 1,000,000,000. A specified width larger than this produces an error.

- -Pattern_count {SCan_test | CHain_test | ALl}

  A switch and literal pair that specifies using the total number of patterns generated by the tool when the variable is dynamic. Note that when you use this switch, you're aren't allowed to specify a value_string. Choose from one of the following:

  SCan_test — Scan patterns.

  CHain_test — Chain patterns.

  ALl — Both scan and chain patterns.

- -LSB_shifted_first

  An optional switch that specifies shifting the less significant bit first into the register.

- -INput_pin_inversion

  An optional switch that specifies an inversion on the input pin when loading the register.

- -OUtput_pin_inversion

  An optional switch that specifies an inversion on the output pin when unloading the register.

Example

The following example deletes all register value variables and then specifies two dynamic register value variables with a decimal radix and register width of 37.

delete_register_value -all

add_register_value setup_TDI1 0 -dynamic -radix decimal -width 37

add_register_value setup_TDI2 10 -dynamic -radix decimal -width 37

report_register_value

```
//  Register value name                value string                width
//  -------------------  -------------------------------------  -----
//       setup_TDI1      0000000000000000000000000000000000000   37
//       setup_TDI2      0000000000000000000000000000000001010   37
```

add_scan_chains

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Prerequisites: You must define the scan chain group with the add_scan_groups command prior to using this command.

Usage

add_scan_chains [-Internal | -Load_only] {***chain_name group_name input_pin output_pin***}...

For “dft -edt” context

add_scan_chains [-Internal] {***chain_name group_name input_pin output_pin***}...

Description

Specifies a name for a pre-existing scan chain within the design.

The add_scan_chains command defines a scan chain that exists in the design. A scan chain references the name of a scan chain group, which you must define prior to issuing this command.

A pre-existing scan chain is a serially connected set of scan cells that has been stitched together in a previous scan insertion operation, or that you created manually. In order for the tool to be able to correctly insert scan elements in the remainder of the design or to run rules checking on existing scan circuitry, you need to notify the tool of this circuitry, so it can treat those elements in the chain differently than the elements in the rest of the design.

When you use this command to notify the tool of a pre-existing scan chain, dft -scan context removes the scan cells in the scan chain from the eligible scan elements list. Because the tool removes the scan cells in the scan chain from the scan candidate list, the rules checker does not perform the usual scannability checks on those scan cells. However, the rules checker does perform additional rules checking based on the declaration of pre-existing scan elements that pertain to the checking of the validity and the operation of that scan chain.

If the design does have a pre-existing scan chain that you declare with the add_scan_chains command, you need to provide information on the operation of that scan chain in a test procedure file.

Arguments

- ***chain_name***

  A required repeatable string that specifies the name of the scan chain to add to the specified scan group.

- ***group_name***

  A required repeatable string that specifies the name of the scan chain group to add the specified scan chain to.

- ***input_pin***

  A required repeatable string that specifies the input pin of the specified scan chain.

- ***output_pin***

  A required repeatable string that specifies the output pin of the specified scan chain.

- -Internal

  An optional switch that defines internal scan chains.

Note

The -Internal switch specifies compressed scan chains when using Tessent TestKompress with EDT logic. Do not use it to define uncompressed scan chains (chains connected directly to a primary input and primary output and not driven by or observed through the Tessent TestKompress logic). See the "Scan Chain Insertion" section in the *Tessent TestKompress User's Manual*.

- -Load_only **(Not supported in the hybrid TK/LBIST flow)**

  An optional switch that specifies the definition of a load-only scan chain which is an uncompressed scan chain in which the scan input is a primary input and the scan output is an internal pin that is only used for the purpose of scan chain tracing, A load_only scan chain does not need to be unloaded which saves chip-level pins and scan data.You can specify a load_only scan chain for special cases such as on-chip clock controllers that only need to be loaded but do not need to be unloaded.

  The tool automatically adds OX constraints on all cells of the chain using the chain masking mechanism, since those cells will not be unloaded and observed. In the generated patterns or mode_external testbench, the internal scan chain outputs are ignored. These chains can be added with other normal scan chains, and/or with EDT blocks. However, the load-only chains must be uncompressed and loaded only from ports, not a decompressor.

Note

This switch does not support mapping EDT patterns to single bypass chain mode. Also, just like normal uncompressed chains, load-only uncompressed chains should not be added during the EDT IP phase.

Example 1

The following example defines two scan chains (chain1 and chain2) that belong to the scan group (grp1):

```
add_scan_groups grp1 atpg.testproc
add_scan_chains chain1 grp1 si1 so1
add_scan_chains chain2 grp1 si2 so2
```

Example 2

The following example shows add_scan_chains commands similar to those Tessent TestKompress would write in the **_edt.dofile* dofile, during the IP Creation Phase, for the two

scan chains of the preceding example. By default, the top level module name "/my_design" is prefixed to the pin names.

```
add_scan_groups grp1 *_edt.testproc
add_scan_chains -internal chain1 grp1 /my_design/si1 /my_design/so1
add_scan_chains -internal chain2 grp1 /my_design/si2 /my_design/so2
```

Related Commands

add_scan_groups
delete_scan_chains
report_scan_chains

add_scan_groups

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

add_scan_groups {***group_name test_procedure_filename***}...

Description

Specifies a group name for a set of pre-existing scan chains in a design. Only one group name can be specified per session.

If the design has pre-existing scan chains, those scan chains must belong to a scan group. The add_scan_groups command also specifies the corresponding test procedure file for that scan group. A sequence of procedures in the test procedure file defines the operation of the scan chains within a scan group. The scan group must have a corresponding test procedure file.

When needed, you can also use the add_scan_groups command to provide initialization values for non-scan memory elements. If the design does not have pre-existing scan chains and you need to initialize some non-scan memory elements for scannability checking, you can specify “dummy” as the group_name along with a test_procedure_filename. Then, within the test procedure file, you can use the optional **test_setup** procedure to initialize the non-scan memory elements.

As a result, in dft -scan context, the tool models the non-scan memory elements as a TIE1 or TIE0.

Note

You must also define these same elements as non-scan using the add_nonscan_instances command.

Arguments

- ***group_name***

  A required string that specifies the name of the scan chain group that you want to add to the system.

- ***test_procedure_filename***

  A required string that specifies the name of the test procedure file that contains the information for controlling the scan chains in the specified scan chain group.

Example

The following example defines a scan chain group, group1, which loads and unloads a set of scan chains, chain1 and chain2, by using the procedures in the file, *scanfile*:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 testout2
add_scan_chains chain2 group1 indata4 testout4
```

Related Commands

write_procfile

add_scan_instances

Context: dft -scan, dft -test_points

Mode: setup

Usage

add_scan_instances ***pathname***… | ***instance_expression***
[-INStance | -Module]

Description

Adds specified instances to the scannable instance list.

When inserting scan chains, the add_scan_instances command ensures that the tool includes specific sequential instances in the scan list. The tool generates the scan list during the scan identification process. If the specified instance does not pass the rules checking process, it is not included in the identified scan list.

You can use the delete_scan_instances command to remove the exception status that you have attached to an instance with the add_scan_instances command. In this case, although the instance is converted back into a non-scan instance, the effects of its previous unknown state on downstream instances is not reset.

Arguments

- ***pathname***

  A required repeatable string that specifies the pathnames of the sequential instances to add to the scan instance list. If the specified instance is hierarchical, then all sequential instances beneath it are also added to the scan list.

- ***instance_expression***

  A required string representing a list of instances within the design. The string instance_expression is defined as:

  { string | string * } ...

  The asterisk (*) can be used as a wildcard character. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. If you use a pathname expression to select several instances, the tool will add_scan_instances for all the pins on those instances; but if the expression specifies a location below the instance level of an ATPG library model, an error message displays.

- -INStance | -Module

  An optional switch that specifies whether the specified pathnames are instances or modules. The default is -INStance.

Examples

The following example adds two sequential instances to the identified scan list and then runs the scan identification process.

```
add_scan_instances i_1006 i_1007

insert_test_logic -number 10
```

Related Commands

delete_scan_instances

report_seq_transparent_procedures

add_scan_models

Context: dft -scan, dft -test_points

Mode: setup

Usage

add_scan_models ***model_name***…

Description

Specifies that the tool is to flag every instance of the named DFT library model for inclusion into the identified scan list.

If the tool is inserting scan chains, then the add_scan_models command ensures the tool includes all instances of a specific sequential DFT library model in the scan list. The tool generates the scan list during the scan identification process, which you initiate with the insert_test_logic command in the analysis mode. The tool subsequently replaces all instances in the scan list with the equivalent DFT library scan model during scan synthesis, which you initiate with the insert_test_logic command while you are in analysis mode.

If the tool is in the analysis mode, then the add_scan_models command only flags the scannable instances of the specified library model for inclusion into the scan list. Scannable instances are those sequential instances previously passing all the scannability checks run by the Design Rule Checker when you placed the tool into the analysis mode. The tool omits library model instances from the scan list if the instance fails the design rule checks.

The add_scan_models command flags all instances of the specified sequential DFT library model, where the add_scan_instances command only individually flags sequential design instance(s).

Arguments

- ***model_name***

  A required, repeatable string specifying the model names that you want to add to the scan model list. Enter the model names as they appear in the DFT library.

Examples

The following example flags all instances of the specified DFT library model for inclusion into the scan list.

```
add_scan_models dff1a
set_system_mode analysis
insert_test_logic -number 10
```

Because of the previous setup in this example, when the tool runs the scan identification process, it chooses the optimal 50 percent of eligible scan instances, ensuring that it includes all eligible instances of the dff1a model in that 50 percent of identified scan instances.

delete_scan_models

report_scan_models

add_scan_partition

Context: dft -scan

Mode: setup, analysis

Usage

add_scan_partition ***object_name*** **-INstance** {***pathname...*** | ***instance_expression...***} **-MOdule** ***module_name...*** **-LIbrary_model** ***library_model_name...*** [-NUmber *integer* | -MAx_length *integer*] [-EDT] [-VErbose]

Description

Specifies a grouping of scan cells (a partition) in which scan chains are inserted separately from the remaining scan cells in the design.

The remaining cells are placed into a default scan partition called default_scan_partition. If a module instance name is supplied in the list of instances, all sequential instances hierarchically under this given module instance are added to the scan partition. If a module name is supplied, all instances of that module and the sequential instances hierarchically under these instances are added to the scan partition. If a library model name is supplied, all instances of this library model are added to the scan partition if this library model is defined for a sequential instance. At least one of the -INstance, -MOdule, and -LIbrary_model switches should be supplied. They can also be supplied together in the same command line.

It is advisable to add scan partitions in Setup mode, especially when the partitions require dedicated scan enable signals that, preferably, should be defined in Setup mode or when a power data is read in into the design. In the case of power data, the specified power domains are mapped into scan partitions during transition from Setup mode to analysis mode; so, it is important to make sure that there are no conflicts between the power domains and user-defined scan partitions.

The specified group of cells is placed in scan chains based on the number of chains or the maximum chain length option specified with this command, along with the -clock/-edge merge options of the insert_test_logic command. The -number and -max_length options of the insert_test_logic command apply to the entire design as follows:

- The -number value specified by add_scan_partition cannot exceed the -number value specified by insert_test_logic; if -number is not specified by add_scan_partition, a single chain is inserted for the partition by default.
- If the -max_length value is not specified by add_scan_partition, the -max_length value of insert_test_logic is used to generate the partition's scan chains.

Note

You can specify either a number chain specification or a maximum length chain specification in a single session among the insert_test_logic, add_scan_partition, and set_wrapper_chains commands, but, you cannot specify both. For example, if you specify the number of chains for a scan partition using the add_scan_partition -number option, you cannot use the insert_test_logic -max_length option for the remainder of the scan cells.

The tool generates a single dofile and testprocedure file even if there are multiple scan partitions defined. However, in the dofile, the scan chain declarations of the same scan partition are separated from the other groups of scan chain declarations by a comment line which indicates the scan partition name. Also, the groups of scan chain declarations are in the same order as the defined scan partitions. If the -Edt switch is used, the tool writes out the Tessent TestKompress command, “Add Edt Block name”, before every group of scan chain declarations, where name is the name of the scan partition specified by object_name.

Default scan pin naming for each partition cannot be specified by means of the set_scan_pins command. However, individual scan pin naming per chain can be specified by means of the add_scan_pins command. This gives the control over scan pin naming for each scan partition since scan chains are created in the order the scan partitions are defined and the number of scan chains for each scan partition is known.

Note

The scan cells of subchains cannot be included in scan partitions. This is because a subchain container can be a blackbox instance, the sequential cells of which do not exist in the netlist. Therefore, subchains can be included in scan partitions by specifying the pathname of their container module instances, or the module name of the container modules.

Arguments

- ***object_name***

  A required string that specifies a name for the scan partition.

- **-INstance** {***pathname...*** | ***instance_expression...***}

  A required switch and a repeatable string that specify the pathname(s) of the sequential instances that you want to place into the scan partition. If a module instance pathname is specified, all sequential instances hierarchically under that instance are added to the partition. This switch can be used along with the -Module and -Library_model switches (and their arguments) in the same command line. However, all three cannot be omitted.

  The repeatable string can be in the form of an absolute instance pathname or a pathname in regular expression form. This argument does not support pathnames to objects below the instance level of an ATPG library model. If the instance pathname/expression cannot be

mapped to any sequential element in the design, the tool generates an error message. The string instance_expression is defined as:

{string | string *} ...

The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

- **-MOdule *module_name...***

  A required switch and a repeatable string that specify the module name(s) of the instances that are the containers of the sequential instances that you want to place into the scan partition. All sequential instances hierarchically under these container instances are added to the partition. This switch can be used along with the -Instance and -Library_model switches (and their arguments) in the same command line. However, all three cannot be omitted.

- **-LIbrary_model *library_model_name...***

  A required switch and a repeatable string that specify the library model name(s) of the sequential instances that you want to place into the scan partition. This switch can be used along with the -Instance and -Module switches (and their arguments) in the same command line. However, all three cannot be omitted.

- -NUmber *integer*

  An optional switch and integer pair that specify the exact number of scan chains that you want the tool to insert for the scan partition specified. Final results depend upon the number of scan candidates. The default number of chains is 1.

Note

The number of scan chains specified with insert_test_logic -number applies to the entire design. The number of scan chains specified with other commands such as set_wrapper_chains and add_scan_partition is subtracted from this number.

The total number of all scan chains individually specified with the set_wrapper_chains and add_scan_partition commands cannot exceed the number specified by the “insert_test_logic -number” command.

- -MAx_length *integer*

  An optional switch and integer pair that specify the maximum number of scan cells that the tool can stitch into each new scan chain; this argument overrides the -max_length value of the insert_test_logic command which is applied to the entire design. The tool evenly divides the scan cells into scan chains the length of which does not exceed the -max_length value of the add_scan_partition command; if -max_length is not specified, the -max_length value of the insert_test_logic command is used, if provided; otherwise, a single chain is inserted for the partition by default. Final results depend upon the number of scan candidates.

- -EDT

  An optional switch that specifies the tool to write out the Tessent TestKompress command "Add Edt Block name" before each group of scan chain declarations in the dofile written out by the tool. In the dofile, the scan chain declarations of the same scan partition are grouped together and separated from the other groups of scan chain declarations by a comment line. The "name" string in the Tessent TestKompress command is the same as the scan partition name specified by object_name.

- -VErbose

  An optional switch that turns on verbose transcript printing. When specified, the pathnames of the sequential cells included in the scan partition are printed in the session transcript.

Examples

In the following example, two scan partitions are defined. The first partition, partA, is defined using exact pathnames of the sequential instances, and the second partition, partB, is defined by the container module instance of the sequential instances. A single scan chain is inserted by default for partA, whereas two scan chains are inserted for partB. Two scan chains are inserted for the remaining cells in the default scan partition, as specified by the -number argument of the insert_test_logic command. The -Edt switch is used for partA, allowing the tool to write out the Tessent TestKompress command, Add Edt Block, in the dofile, in addition to the scan chain declarations. Also, Individual scan I/O pins per chain and default scan I/O pin naming are specified by means of the add_scan_pins and set_scan_pins commands, respectively.

```
add_clocks 0 clk1
add_scan_partition  partA  -instance udff1 umodA/udff32 umodB/udff5 -edt   # 1 chain
add_scan_partition  partB  -instance umodC  -number 2 -edt   # 2 chains

add_scan_pins  chain1  partA_chain1_si  partA_chain1_so
add_scan_pins  chain2  partB_chain1_si  partB_chain1_so
add_scan_pins chain3 partB_chain2_si  partB_chain2_so
set_system_mode analysis
set_scan_pins  input  -indexed  -prefix mysi  -initial 1
set_scan_pins  output  -indexed  -prefix myso  -initial 1
insert_test_logic -number 5     # 2 chains inserted for the default scan partition
write_atpg_setup fscan
```

So, a total of five scan chains are inserted. After mapping the individual scan I/O pins per chain, new scan I/O pin names are generated for the remaining chains based on the specified default pin naming. The dofile generated by the tool looks similar to the one below. Note that the scan chain declarations of each scan partition are denoted by a comment line. The order of the groups of declarations is the same as the order of the scan partition declarations. The default scan partition chains are printed as the last group. Also note that the Tessent TestKompress add_edt_blocks commands are written out since the -Edt switch is used. For the default scan partition, the tool generates the name "edt_top_block" to use it as the edt block identifier string in the add_edt_blocks command.

```
add_scan_groups grp1 fscan.testproc

# The scan chains of scan partition "partA"
add_edt_blocks partA
```

```
add_scan_chains chain1 grp1 partA_chain1_si  partA_chain1_so
# The scan chains of scan partition "partB"
add_edt_blocks partB
add_scan_chains chain2 grp1 partB_chain1_si  partB_chain1_so
add_scan_chains chain3 grp1 mysi1 myso1
# The scan chains of scan partition "default_scan_partition"
add edt block edt_top_block
add_scan_chains chain4 grp1 mysi2 myso2
add_scan_chains chain5 grp1 mysi3 myso3

add_clocks 0 clk1
```

report_scan_partitions

add_scan_pins

Context: dft -scan

Mode: setup, analysis

Usage

add_scan_pins ***chain_name scan_input_pin scan_output_pin***

Description

Declares the name of a scan chain at the top-level module and assigns the corresponding scan input pin, scan output pin, and optionally, scan clock pin you associate with the chain.

Tip: For information on assigning scan pins to scan chains and the fixed-order file, refer to "Naming Scan Input and Output Ports" in the *Tessent Scan and ATPG User's Manual*.

If you specify nonexistent signal names for the scan input or scan output pins, the tool generates a warning and adds the appropriate pins when you perform scan synthesis with the insert_test_logic command.

The tool uses the default names when generating the scan chain. The default name of the scan chain is chain1, with the corresponding scan input pin named scan_in1 and the corresponding scan output pin named scan_out1. If the tool inserts multiple scan chains, the default naming increments the numerical suffix of each argument by one for each chain, such as chain2, scan_in2, and scan_out2.

Each use of the add_scan_pins command specifies the naming for a single scan chain. You can optionally use the set_scan_pins command to globally set the default naming conventions for scan chains that do not use existing design pins.

Arguments

- ***chain_name***

  A required string that specifies the name of the scan chain with which you want the tool to associate the *scan_input_pin* and *scan_output_pin* names.

- ***scan_input_pin***

  A required string that specifies the scan input pin name of the scan chain. This pin can be a top-level input pin, top-level bidirectional pin, or an internal signal.

  In addition to a primary input pin name (for example, scan_in), you can also specify an internal instance pin pathname as the scan_input_pin value. If you do so, that pin pathname must be an output pin of an instance. For example, you could use an internal instance pin pathname "/I116/d", where "I116" is the instance name of the I/O cell and "d" is the pin name. If the specified internal instance pin cannot be traced back to a primary input pin through a simple path (only inverters or/and buffers), when the write_atpg_setup command is issued, a warning message is written to the top of the ATPG dofile and the following

command is added prior to the add_scan_chains command referencing the internal scan_input_pin argument:

add_primary_input -internal scan_input_pin

Example 1 shows the content written to the ATPG dofile in this case.

If the pin is a top-level bidirectional pin, the tool assumes that you configured the pin to operate as an input during the scan test and does not check for correct configuration.

- ***scan_output_pin***

  A required string that specifies the scan output pin name of the scan chain. This pin can be any of the following:

  - a top-level output pin
  - a top-level bidirectional pin (single driver)
  - an internal signal

Note

If the scan output pin you specify has a functional connection, the tool multiplexes this connection with the connection line from the last scan cell of the scan chain.

In addition to a primary output pin name (for example, scan_out), you can also specify an internal instance pin pathname (for example, "/I116/q") for the scan_output_pin value, providing this pin pathname is an input pin of an instance. If the specified internal instance pin cannot be traced forward to a primary output pin through a simple path (only inverters or/and buffers), when the write_atpg_setup command is issued, a warning message is written to the top of the ATPG dofile and the following command is added prior to the add_scan_chains command referencing the internal scan_output_pin argument:

add primary output scan_output_pin

Example 2 shows the content written to the ATPG dofile in this case.

If the pin is a top-level bidirectional pin, the tool assumes that you configured the pin to operate as an output during the scan test and does not check for correct configuration.

Example 1

The following example specifies an internal pin pathname that the tool cannot trace back to the primary input. See the resulting dofile contents in Example 7-1 on page 536.

```
add_clocks 0 clk

set_tristate_gating bus -control ten
set_tristate_gating out1 out4 -control ten
set_tristate_gating out3 out2
set_bidi_gating on

add_scan_pins c1 udff1/Q tbus2_drv1/A
add_scan_pins c2 bidi_1/X tbus1_drv2/A
```

```
set_system_mode analysis
report_dft_check -tristate
insert_test_logic -number 2
report_scan_chains
write_atpg_setup results/tri_on_ten -replace

add_simdut_fault

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

add_simdut_fault **-signal *signal_name* -fault [0 | 1]**

Description

Injects a stuck-at-0 fault or a stuck-at-1 fault into the specified signal for SimDUT simulation.

SimDUT uses the Verilog simulation capabilities to force the signal to 0 or 1. The Verilog capability has the following behavior: When you specify a pin pathname for the fault you want to inject, Verilog forces the associated signal to the specified value.

When you inject a fault at a specific pin pathname, SimDUT actually injects the fault at the whole net, not only on the specific pin. The fault acts like a fault injected on the upstream driver pin of the associated net. If you specify the input port of a cell and this port is attached to a net with fanout, then the fault acts like a fault injected on the driver port of that net.

When you execute a test, SimDUT simulates the injected fault as if it were an actual defect in silicon, collects the simulated failing cycles, and returns the results.

You can execute this command multiple times. When you specify a particular signal more than once, the last command that specifies the signal overrides all previous specifications. For example, if you first add a stuck-at-0 fault to signal A and later add a stuck-at-1 to signal A, SimDUT only adds the stuck-at-1 fault to signal A.

Arguments

- **-signal *signal_name***

A required switch and string pair that specifies the name of a signal from the Verilog netlist. Refer to "SimDUT Signal Naming Convention" in *Tessent SiliconInsight User's Manual for Tessent Shell* for more information

- **-fault [0 | 1]**

  A required switch and literal that specifies the fault type as follows:

  0 - Specifies stuck-at fault type SA0.

  1 - Specifies stuck-at fault type SA1.

Example

The following example injects an SAO fault into the SIMDUT_TB.CHIP.memory00.q_a signal.

```
add_simdut_fault -signal SIMDUT_TB.CHIP.memory00.q_a -fault 0
```

Refer to "Performing SimDUT Test Pattern Simulation" in *Tessent SiliconInsight User's Manual for Tessent Shell* for a usage scenario.

add_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

add_simulation_context ***context_name***

Description

Creates a new user-defined simulation context.

The add_simulation_context command allows you to create a new user-defined simulation context in which the tool can perform simulation and introspection. Initially, the tool propagates tied values, such as power and ground, and then sets the remaining simulation values to X. The command automatically sets the new simulation context to be the current simulation context.

Arguments

- ***context_name***

  A required string that specifies the name of the context. The context_name has to be different than one of the predefined context names listed in Table 7-40 on page 1648.

Example

The following example shows how to create a new simulation context:

```
SETUP> add_simulation_context myContext
//  'myContext' is the current simulation context.

SETUP> get_simulation_context_list -user_defined
{myContext}
```

add_simulation_force

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

add_simulation_force ***obj_spec*** -value ***value***

Description

Forces one or more gate_pin objects to the specified value.

The add_simulation_force command forces the specified gate_pin object(s) to the specified force value within the current simulation context. The actual simulation is not triggered until you issue the simulate_forces or simulate_clock_pulses command. If a specified gate_pin object has already been forced by an earlier add_simulation_force command, and the tool hasn't yet simulated the previous force, the new force value overwrites the existing one in case of a conflicting value. Note that adding a simulation force also updates the gate_pin attribute named simulation_value.

This command is allowed for user-defined simulation contexts only.

Arguments

- ***obj_spec***

  A required value that specifies one or more gate_pin objects.

- -value ***value***

  A required switch and value pair that specifies the force value applied to the specified gate_pin objects. The value is allowed to be one of the following: X, 0, 1, or Z.

Example

The following example shows the effect of adding a force on a particular gate_pin object, and then triggering the tool to simulate that force:

ANALYSIS> **set_current_simulation_context myContext**
ANALYSIS> **add_simulation_force [get_gate_pins I1] -value 1**
ANALYSIS> **report_simulation_forces**

```
Value   Object
------  ------
1       I1
```

ANALYSIS> **get_simulation_value_list [get_gate_pins I1]**
{ X }

ANALYSIS> **simulate_forces**
ANALYSIS> **get_simulation_value_list [get_gate_pins I1]**
{ 1 }

add_sub_chains

Context: dft -scan, dft -test_points

Mode: setup

Usage

add_sub_chains ***object_name subchain_name scan_input_pin scan_output_pin length scan_type* [-Module | -Library_model | -Instance]** [-TEN *test_enable_pin* {0 | 1}] [-NO_Reordering] [-TYpe {None | Core | Input_wrapper | Output_wrapper}] [-EXTest_enable_pin *pinname*] [-Lockup_cell_at_output]

Description

Specifies a pre-existing scan chain (subchain) within a module, library model, instance, blackbox, or empty module in a hierarchical design to be stitched into the top-level scan chain during the stitching process.

Note

An empty module is a module defined in the netlist without any content; that is, it consists of only the input and output port definitions.

The tool checks the traceability of an added subchain like any other pre-existing scan chain if the subchain's container is an instance of a netlist module, is not blackboxed, and a test procedure file containing a shift and load_unload procedure is present. If a test procedure file is not present, the following warning message is issued and the modules where the added subchains reside are treated as black boxes:

```
// Warning: Unable to find load_unload and shift procedures: subchains
// tracing will not be done. Subchain containers will be treated as black
// boxes.
```

Any sequential cell inside a traceable subchain's container that is not a part of this subchain is treated as any other sequential cell in the design.

The scan_input port of a subchain must be either unconnected or tied to 0 or 1 or connected to the scan_output port of this subchain either directly or via buffers. During the scan chains stitching, the latter loop is broken; any buffers of the original loop are retained in the scan_output connection. The scan_output port of a subchain must be either unconnected or connected to the scan_input port of this subchain either directly or via buffers.

The scan_enable port, specified in scan_type, can be either unconnected or tied to 0 or 1.

Every subchain specification in Mux-DFF scan architecture must be accompanied by the subchain's clock definition (see add_subchain_clocks).

Every subchain is subject to S-rules checking during DRC.

During the block-by-block test logic insertion in the bottom-up design flow, the tool can write the subchain setup information to a file with the write_subchain_setup command at the lower design levels. This setup file, containing the add_sub_chains command for every top-level scan

chain at the lower design level, can be used as part of the setup at the higher design level to have the pre-existing lower design level scan chains (subchains) stitched into the new top-level scan chains.

Arguments

- ***object_name***

  A required string that specifies either the pathname of an instance, the name of a module, or the name of a library model. The object_name is the container where the subchain resides.

- ***subchain_name***

  A required string that specifies a name for the scan subchain. A unique subchain name should be used for each add_sub_chains command.

- ***scan_input_pin***

  A required string that specifies the scan input pin of the scan subchain.

- ***scan_output_pin***

  A required string that specifies the scan output pin of the scan subchain.

- ***length***

  A required integer that specifies the number of scan cells in the scan subchain.

- ***scan_type***

  Scan type usage:

  {Mux_scan {*scan_enable* [INVerted]}} |
  Clocked_scan *scan_clock* | Lssd *master_clock slave_clock*

  A required literal and multiple argument option that specifies the scan type and control of the scan subchain. Options include:

  - **Mux_scan *scan_enable*** [INVerted]
    Required switch, string, and literal that specifies the type, name, and internal inversion of the scan enable pin on the subchain container (module or library_model).

  - **Clocked_scan *scan_clock*** — A required literal and string pair that specifies the clocked-scan style of scan cells and the name of the scan clock for the scan subchain.

  - **Lssd *master_clock slave_clock*** — A required literal and two-string triplet that specifies Level-Sensitive Scan Design and the names of the master and slave clocks, respectively, for the scan subchain.

- -Module | -Library_model | -Instance

  An optional switch that specifies the type of the subchain container specified by the object_name argument. The container can then be a module (-Module), a library model (-Library_model), or an instance of a module/model (-Instance). The default type is -Module.

- -TEN *test_enable_pin* {0 | 1}

  An optional switch, string, and literal pair that specifies the test enable pin added in the sub-module that you want connected to the corresponding pin in the top module. The active value can be 0 or 1.

- -NO_Reordering

  An optional switch that specifies to keep the order of cells on the specified subchain's scan path intact when writing out the scanDEF file by placing them into an ORDERED section of the corresponding scan chain. When this switch is not specified, the subchain's sequential cells are written into a FLOATING section of the corresponding scan chain which allows them to be reordered.

- -TYpe {None | Core | Input_wrapper | Output_wrapper}

  An optional switch and a literal that specify the type of scan chain the subchain should be stitched into.

  This information is used to override the automatic identification of the scan chain type for this subchain's stitching into either a Core type, Input wrapper type, or Output wrapper type scan chain. The Input_wrapper and Output_wrapper types are applicable only in the wrapper chains flow triggered by the analyze_wrapper_cells command.
  When this switch is not specified, the tool automatically determines the scan chain type of a traceable subchain whenever possible (see the -INClude_sub_chains {ON | OFF} option of set_wrapper_chains). When this switch is specified with the explicit Input_wrapper, Output_wrapper or Core type, and the analyze_wrapper_cells command has been issued, the subchain is stitched into the appropriate Input, Output or Core chain. In any case, the subchain will be controlled by a scan enable signal appropriate to the type of the scan chain it is stitched into.

- -EXTest_enable_pin *pinname*

  An optional switch and string pair that specifies the extest enable pin on the subchain container module boundary. This switch is only valid when the -Type argument is specified as Wrapper because this pin is only used for wrapper type subchains.

- -Lockup_cell_at_output

  An optional switch that indicates when a lockup cell is present at the end of a sub chain (to avoid insertion of a new lockup cell during the stitching of sub chains at the top level in bottom-up flow). You can add this switch manually; the tool automatically adds this switch when writing out existing scan chains with the write_subchain_setup command.

Example 1

The following example defines a subchain on a sub-module:

```
add_sub_chains addr subc1 scan_in1 scan_out1 8 mux_scan  scan_en inverted
add_subchain_clocks subc1 0 ck -first_cell_clock -leading_edge
add_subchain_clocks subc1 0 ck -last_cell_clock -leading_edge
report_sub_chains
```

```
mux_scan: addr subc1 8 scan_in1 scan_out1 scan_en (inverted)
```

Example 2

The following example shows information written out by the report_scan_cells command following by the same information as it appears when it is written to the scan DEF file.

```
add_sub_chains wrapA schi1 scan_in1 scan_out1 1 mux_scan sen

add_subchain_clocks

Context: dft -scan, dft -test_points

Mode: setup

Usage

add_subchain_clocks ***subchain_name off_state*** {***clock_port_name***...}
[-Set | -Reset | -First_cell_clock | -Last_cell_clock]
[-LEading_edge | -Trailing_edge]

Description

Specifies the clock pins for scan chains within modules, library models, instances, blackboxes, or empty modules of a hierarchical design.

The specified clock pins are added relative to the module boundary, not the top-level of the design. The add_sub_chains command adds subchains to a specific instance or all instantiations of a specific module. When you use the add_subchain_clocks command to specify subchain clock pins on a module, the clock timing information is automatically adjusted for each instantiation of the module based on the connections to the top-level clock pins. The following information is considered to determine the clock timing for each subchain cell.

- Off-state value of the top-level clock pin (Usually specified via the add_clocks command)
- Overall inversions from the top-level clock pin to the clock pin of the subchain instance (Obtained through DRC rule checking of the input netlist)
- Off-state value of the subchain clock pin (Specified by the off_state argument of the add_subchain_clocks command)
- The clock capture edge of the sequential elements inside the subchain cell with respect to the off-state value of the subchain clock pin (Specified by the -leading_edge/-trailing_edge argument of the add_subchain_clocks command)

Note

The incorrect specification of the off_state argument and the -leading_edge/-trailing_edge switches may lead to incorrect placement of the subchain cells in chains, incorrect lockup cell insertion, or incorrect scan cell reporting. When specifying this information, consider all the inversions from the subchain clock pin down to the primitive sequential element inside the subchain instance in order to determine the correct clock capture edge. For further information, see the examples in the following sections.

Scannability analysis DRCs: S1, S2, and S3 validate the defined subchains when you exit Setup mode. Once you specify the subchain clock pins, you must also use set_test_logic to enable the insertion of the test logic to fix any S-rule violations.

Arguments

- ***subchain_name***

  A required string that specifies the name of a subchain previously defined with the add_sub_chains command.

- ***off_state***

  A required string that specifies the off state value for the subchain clock pin. Sequential instances maintain their state when the clock is at the specified value; either 1 or 0.

- ***clock_port_name***

  A required, repeatable string that specifies the clock pins on the subchain that must be controlled during scan chain shifting.

- -Set

  An optional switch that specifies the clock pins listed by the clock_port_name argument are *set* signals for cells in the subchain and should be held in the off state during scan chain shifting.

- -Reset

  An optional switch that specifies the clock pins listed by the clock_port_name argument are reset signals for cells in the subchain and should be held in the off state during scan chain shifting.

- -First_cell_clock

  An optional switch that specifies the clock pin listed by the clock_port_name argument drives the first cell in the subchain.

- -LAst_cell_clock

  An optional switch that specifies the clock pin listed by the clock_port_name argument drives the last cell in the subchain.

- -LEading_edge

  An optional switch that specifies the clock pin listed by the clock_port_name argument updates cells on the leading edge of the off-state to on-state transition. This value is only valid for defining the first and/or last cell clocks. This is the default value.

- -Trailing_edge

  An optional switch that specifies the clock pin listed by the clock_port_name argument updates cells on the trailing edge of the off-state to on-state transition. This value is only valid for defining the first and/or last cell clocks.

Example 1

The following example illustrates correct specification of the off_state argument along with -leading_edge/-trailing_edge switches. It also shows how clock capture edge is calculated by the tool.

The input netlist is given as below to insert scan chains to module TOP. Scan chains were inserted to modules A and B in previous sessions of the tool.

```
module TOP (tclk1, tclk2);
   input tclk1, tclk2;
      invx inv (.A(tclk1), .Y(tclk1_n));
      A    uA (.clk(tclk1_n));
      B    uB (.clk(tclk2));
   endmodule

   module A (clk, si, sen, so);
   input clk, si, sen;
   output so;
      invx inv (.A(clk), .Y(clk_n));
      sffn ff1 (.CK(clk_n), .SI(si), .SE(sen), .Q(net1));
      sffn ff2 (.CK(clk), .SI(net1), .SE(sen), .Q(net2));
      sffn ff3 (.CK(clk), .SI(net2), .SE(sen), .Q(so));
   endmodule

   module B (clk, si, sen, so);
   input clk, si, sen;
   output so;
      sffn ff1 (.CK(clk), .SI(si), .SE(sen), .Q(net1));
      sffn ff2 (.CK(clk), .SI(net1), .SE(sen), .Q(so));
   endmodule
```

The library model implementation for the scan flop 'sffn' is given below.

```
model sffn (D, SI, SE, CK, Q) (
   scan_definition (
      type = mux_scan;
         data_in = D;
      scan_in = SI;
      scan_enable = SE;
      scan_out = Q;
      non_scan_model = dffn (D, CK, Q);
   )
   input (D, SI, SE) ()
   input (CK) (negedge_clock)
   output(Q) (
         primitive = _inv (CK, CK_n);
         primitive = _mux (D, SI, SE, _D);
         primitive = _dff(, , CK_n, _D, Q, );
      )
   )
```

The top module shift clocks are defined as below.

add_clocks 0 tclk1
add_clocks 1 tclk2

The subchains on modules A and B are defined as below. The first flop of subchain 'subch1' (/uA/ff1), for example, is defined as trailing-edge with respect to the subhchain clock pin 'clk'. This edge value is calculated considering the off-state value of the subchain clock pin, the

inversion from the subchain clock pin to the subchain flop instance '/uA/ff1', and the inversion from the subchain flop instance clock pin to the _dff primitive inside the library model 'sffn'.

add_sub_chain A subch1 si so 3 mux_scan sen
add_subchain_clock subch1 1 clk -trailing_edge -first_cell_clock
add_subchain_clock subch1 1 clk -leading_edge -last_cell_clock
add_sub_chain B subch2 si so 2 mux_scan sen
add_subchain_clock subch2 0 clk -trailing_edge -first_cell_clock
add_subchain_clock subch2 0 clk -trailing_edge -last_cell_clock

After scan insertion for top module, the following is reported. Note that the cells of subchain 'subch2' are defined as trailing_edge, however, the tool adjusted the clock capture edge (ClockPolarity) as '+' based on the subchain's connection to the top module clock pin 'tclk2', with an off-state value of '1'. The clock capture edges for subchain 'subch1', remain the same with respect to the top module clock pin 'tclk1', since subchain clock pin is connected to the top module clock pin with an opposite off-state value through an inverter.

```
//  command: report_scan_cells
-------------------------------------------------------------------------
CellNo ChainName GroupName Pathname CellName ScanOut Clock ClockPolarity
-------------------------------------------------------------------------
   0 chain1 (subch1) grp1 /uA/ff3  sffn     Q       tclk1 (+)
   1 chain1 (subch1) grp1 /uA/ff2  sffn     Q       tclk1 (+)
   2 chain1 (subch1) grp1 /uA/ff1  sffn     Q       tclk1 (-)
   0 chain2 (subch2) grp1 /uB/ff2  sffn     Q       tclk2 (+)
   1 chain2 (subch2) grp1 /uB/ff1  sffn     Q       tclk2 (+)
-------------------------------------------------------------------------
```

Example 2

The following example defines a subchain on a library model and reports the subchain clocks. Note that all the clocks are defined.

add_sub_chains MULTIBITSFF3 chain1 SI SO 16 mux_scan S library_model
add_subchain_clocks chain1 0 RESET -reset
add_subchain_clocks chain1 0 SET -set
add_subchain_clocks chain1 0 Clk_c -first_cell_clock -trailing_edge
add_subchain_clocks chain1 0 Clk_x -leading_edge
add_subchain_clocks chain1 0 Clk_p -leading_edge
add_subchain_clocks chain1 0 Clk_a -last_cell_clock -leading_edge
report_subchain_clocks chain1

```
// clock name type             off_state edge
// ---------- ----             --------- -----
// RESET      reset            0
// SET        set              0
// Clk_c      first cell clock 0         trailing edge
// Clk_x                       0         leading edge
// Clk_p                       0         leading edge
// Clk_a      last cell clock  0         leading edge
```

Example 3

The following example reports the scannability problems of a subchain instance. The subchain is treated as a single sequential instance, but it is listed once for each clock line that needs fixing.

report_dft_check

```
SCANNABLE SUBCHAIN Testlogic /macro MULTIBITSFFX (1)
Set: T /macro/SET1
SCANNABLE SUBCHAIN Testlogic /macro MULTIBITSFFX (1)
Set: T /macro/SET2
SCANNABLE SUBCHAIN Testlogic /macro MULTIBITSFFX (1)
Set: T /macro/SET3
SCANNABLE SUBCHAIN Testlogic /macro MULTIBITSFFX (1)
Reset: T /macro/RESET1
```

All the test logic issues for a specified subchain instance map to a single DRC rule violation. The analyze_drc_violation command displays the entire macro (with an X on each clock line that requires test logic) and arbitrarily displays the driving gate for only one of the pins that requires fixing.

add_subchain_group

Context: dft -scan

Mode: setup

Usage

add_subchain_group ***object_name subchain_name … | subchain_name_expression …***
[-FLexible [-No_floating_cells] | -FIxed]

Description

Adds one subchain group to the system.

The add_subchain_group command specifies a group of subchains in a design so that the tool can stitch these subchains together. If you omit a subchain group, the insert_test_logic command chooses which subchains the tool stitches together. You must have added the subchains (using add_sub_chains) before you specify them as subchains in the argument list.

When adding the subchain groups, you can specify stitching constraints using the following options:

- **-FLexible (default)** — Permits unassigned single flip-flops and subchains in the scan chain for better balancing of top-level scan chains and allows breaking up the subchain group into multiple scan chains when necessary.
- **-FLexible [-No_floating_cells]** — Prevents the mixing of unassigned single flip-flops with subchains from flexible subchain groups in the same scan chain.
- **-Fixed** — Disallows *either* other flip-flops and subchains in the subchain group, or the breaking up of the subchain group. Stitches subchains in the order they are specified in the subchain_name or subchain_name_expression list.

Table 7-7 summarizes the types of subchains that can exist in a design.

Table 7-7. Subchain Types

Subchain Group	Multiple Chain Support	Stitching	Partitioning
No subchain group	Yes	Can be stitched with: • single cells • subchains that are not assigned to any subchain groups • subchains that are assigned to flexible subchain groups	-Clock/Edge merge -Number/Max_length
Flexible	Yes	Can be stitched with: • single cells • subchains that are not assigned to any subchain groups	-Clock/Edge merge -Number/Max_length

Table 7-7. Subchain Types

Subchain Group	Multiple Chain Support	Stitching	Partitioning
Flexible -No_floating_cells	Yes	Can be stitched with: • no other cells or subchains	-Clock/Edge merge -Number/Max_length
Fixed	No	Can be stitched with: • no other cells or subchains	A new scan chain is added per add_subchain_group command

Arguments

- ***object_name***

  A required string specifying the subchain group name.

- ***subchain_name***

  A required repeatable string identifying the subchain name for inclusion into the subchain group. Before identifying the subchain, you must add it with add_sub_chains. You can also report subchain information using report_sub_chains.

  If you added a subchain to a subchain group on a module-based basis, and the module is instantiated multiple times, the tool includes the subchains on all instances of the module in the subchain group when this subchain is specified in the list of subchains of the add_subchain_group command. If the subchains on different instances of the module are to be put into different subchain groups, these subchains need to be added instance-based instead of module-based in order to be assigned a unique subchain name. For more information about adding subchains as module-based versus instance-based, see add_sub_chains.

- ***subchain_name_expression …***

  A required repeatable string in regular expression form that represents a list of subchain names. The regular expression may include asterisk (*), or question mark (?), or wildcard characters.

Note

If a wildcard character is part of a subchain name, you must use the escape character, (\), at the beginning of the name when specifying it as a subchain_name argument for this command. Additionally, you must surround the entire subchain name with curly brackets in order to bypass the Tcl command interpreter. For example, the subchain name sub*?123 should be specified for the subchain_name argument as {sub*\?123}.

The tool adds all subchains whose names match this regular expression to the subchain group specified by the object_name argument.

- **-FLexible** — An optional switch that specifies the type of the subchain group. This is the default. With this option, the tool permits unassigned single flip-flops and subchains in the scan chain for better balancing of the top-level scan chains. Using this option also permits breaking up the subchain group into multiple scan chains when necessary. The tool partitions the subchains of flexible subchain groups along with the scannable flip-flops of the design according to your insert_test_logic command's -Clock/Edge merge and -Number/Max_length options.
- **-FLexible [-No_floating_cells]** — The -No_floating_cells option prevents the mixing of unassigned single flip-flops with subchains from flexible subchain groups in the same scan chain.
- **-Fixed** — In contrast, the -Fixed option disallows either other flip-flops and subchains in the subchain group, or the breaking up of the subchain group. With this option, the subchains of a fixed-type subchain group are placed in a single chain and are not partitioned according to insert_test_logic command options. No other flip-flops or subchains are allowed in the scan chain of a fixed-type group. Note that the subchains of a fixed-type subchain group are stitched into a single scan chain in the order they are specified in the subchain_name or subchain_name_expression list.

Examples

The following example defines a pre-existing scan subchain:

```
add sub chain subblockA subchain1 /scan_in1 /scan_out1 250 \
                    mux_scan /scan_en -module
add sub chain subblockC subchain2 /scan_in1 /scan_out1 120 \
                    mux_scan /scan_en -instance ...
report_sub_chains
```

```
mux_scan: subblockA subchain1 scan_in1 scan_out1 scan_en
mux_scan: subblockC subchain2 scan_in1 scan_out1 scan_en
```

```
add_subchain_group subchaingroup1 subchain1 subchain2 -fixed
```

add_tied_signals

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

add_tied_signals {**0** | **1** | **X** | **Z**} ***floating_object_name***... [-Pin]

Description

Adds a value to floating signals or pins.

The add_tied_signals command assigns a specific value to not-clearly-defined floating signals or pins. If there are floating signals or pins in the design, a warning appears when you leave the setup mode. If you do not assign a specific value, the tool ties the signal or pin values to the default value. To change the default tied value, use the set_tied_signals command.

When you add_tied_signals or pins, the tool places them into the user class. This includes instance-based, blackbox tied signals. When the netlist ties signals or pins to a value, the tool places them into the system class.

Note

The tool will not tie a signal that is connected to bidirectional pins. For example, with a Verilog netlist that has a top level pin named Vdd of type “inout”, you cannot use “add_tied_signals 1 Vdd -pin” to tie Vdd high.

Arguments

- **0**

  A literal that ties the floating nets or pins to logic 0 (low to ground).

- **1**

  A literal that ties the floating nets or pins to logic 1 (high to voltage source).

- **X**

  A literal that ties the floating nets or pins to unknown.

- **Z**

  A literal that ties the floating nets or pins to high-impedance.

- ***floating_object_name***

  A required, repeatable string that specifies the floating nets or pins to which you want to assign a specific value. The tool assigns the tied value to all floating nets or pins in all modules that have the names you specify.

  For pin names, you must include the -Pin switch on the command line; otherwise, the tool assumes the name is a net name.

- -Pin

  An optional switch specifying that the *floating_object_name* argument that you provide is a floating pin name.

Example

The following example ties all floating signals in the circuit that have the net names vcc and vdd, to logic 1 (tied to high):

add_tied_signals 1 vcc vdd

add_to_collection

Context: unspecified, all contexts

Mode: all modes

Usage

add_to_collection ***base_collection object_spec*** [-unique]

Description

Adds objects to a base collection and returns the new collection without affecting the original base collection.

By default, objects that exist in both the base_collection and the object_spec are duplicated in the resulting collection. You can use the -unique switch to remove duplicates.

Arguments

- ***base_collection***

  A required value that specifies the base collection to which objects are to be added. This base collection is copied to a new collection, and objects matching object_spec are added to the new collection. The base_collection can be an empty collection (empty string).

- ***object_spec***

  A required value that specifies an object name, a Tcl list of object names, or a collection of objects to add to the base_collection. The object_spec can be an empty collection (empty string). If object_spec is empty, the result is a copy of the base collection.

- -unique

  An optional switch that removes duplicate objects from the resulting collection. By default, duplicate objects are not removed.

Example 1

The following example adds two collections, a and b, to create a new collection called sum.

```
set a [get_ports a*]
set b [get_ports b*]
set sum [add_to_collection $a $b]
```

Example 2

The following example creates a collection of all nets connected to pins of design instances matching u1/myPrefix*. Note that using the -unique option automatically removes duplicate nets.

```
set sum “”
foreach_in_collection inst [get_instances u1/myPrefix* -of_type design] {
        set inputs [get_pins -of_instance $inst -direction input]
        set outputs [get_pins -of_instance $inst -direction output]
        set sum [add_to_collection $sum [get_fanins $inputs -stop_on net] -unique]
        set sum [add_to_collection $sum [get_fanouts $outputs -stop_on net] -unique]
}
```

Note

This example could have used the append_to_collection command instead, which would have been more efficient because in this example, the intermediate collections are destroyed as soon as they are added.

add_write_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

add_write_controls {**0** | **1**} ***primary_input_pin***...

Description

Specifies the off-state value of the write control lines for RAMs.

The add_write_controls command defines the circuit write control lines and assigns their off-state values. The off-state value of the pins you specify must be sufficient to keep the RAM contents stable.

Note: The tool automatically adds a write control to the clock list during flattening if the flattening process reaches the clock pin of an edge-triggered RAM. In this case, you must ensure that your timeplate includes the waveform for the newly defined clock.

Arguments

- **0**

  A literal specifying 0 is the off-state value for the RAM primary_input_pin.

- **1**

  A literal specifying 1 is the off-state value for the RAM primary_input_pin.

- ***primary_input_pin***

  A required, repeatable string specifying the primary input pins that are write control lines for the RAM and to which you want to assign an off-state value.

Example

The following example assigns an off-state to two write control lines, w1 and w2:

```
add_write_controls 0 w1 w2
set_system_mode analysis
create_patterns
```

analyze_atpg_constraints

Context: dft -edt, patterns -scan

Mode: analysis

Usage

analyze_atpg_constraints {-AUto | -ALl | [{pin_pathname | gate_id# | function_name}... [-Satisfy | -Exclusive]]} [-Bus]

Description

Checks the ATPG constraints you created for their satisfiability or mutual exclusivity.

If you issue the analyze_atpg_constraints command without any arguments, the default is -All. When the command finishes, the tool displays a message that indicates whether the analysis passed, failed, or aborted the ATPG constraint analysis.

Note

With EDT on, Tessent TestKompress support of this command is limited: it will not tell you if a constraint cannot be satisfied with EDT compression. It may also falsely report a constraint can be satisfied.

Arguments

The following lists the three methods for naming the objects for which you want to analyze the constraints. You can use any number of the three argument choices, in any order.

If you only specify an object name when you issue this command, by default, the tool performs the satisfiability (-Satisfy) analysis.

- -Auto

  An optional switch that automatically tries to locate the atpg constraint that cannot be satisfied. The analysis checks to see if any single constraint cannot be satisfied, then reports each constraint that cannot be satisfied (given the current abort limit and other restrictions). Sometimes, each constraint can be satisfied by itself, but some set of constraints cannot all be satisfied. In this case, -Auto switch proceeds to a second analysis where it adds atpg constraints to a set to create a minimal set that can’t be satisfied.

- -ALl

  An optional switch that specifies for the tools to perform the ATPG analysis simultaneously for all the current ATPG constraints. If you do not specify an object name, this is the command default.

- pin_pathname

  A repeatable string that specifies the pathname to the pin on which you are analyzing the constraints.

- gate_id#

  A repeatable integer that specifies the gate identification number of the gate on which you want to analyze the constraints.

- function_name

  A repeatable string that specifies the name of a function you created with the add_atpg_functions command. If you generated the ATPG function with the -Cell option and added constraints with the -Cell option, then the tool also analyzes the constraints on all the cells affected by that ATPG function.

- -Satisfy

  An optional switch that specifies for the ATPG process to attempt to create a pattern that satisfies the selected ATPG constraint. This is the default if you specify an object name without a switch. During the ATPG process, the test generator does not consider the effect of other ATPG constraints or bus contention prevention (unless you use the -Bus switch).

  When the command finishes, the tools display a message that indicates whether the analysis passed (the ATPG process successfully generated a pattern), failed (the ATPG process could not find any possible pattern), or aborted (the ATPG process gave up on trying to find a successful pattern). If the analysis passes, the data that the tool simulated for the pattern is available in parallel pattern zero (0).

- -Exclusive

  An optional switch that specifies for the ATPG process to attempt to create a pattern that sets the selected ATPG constraint at a value different from its constrained value. This test's intent is to ensure that such a pattern does not exist. During the ATPG process, the test generator does not consider the effect of other ATPG constraints or bus contention prevention (unless you use the -Bus switch).

  When the command finishes, the tool displays a message that indicates whether the analysis passed (the ATPG process could not find any possible pattern), failed (the ATPG process found another possible pattern), or aborted (the ATPG process gave up on trying to find a successful pattern). If the analysis fails, the data that the tool simulated for the pattern is available in parallel pattern zero (0).

- -Bus

  An optional switch that specifies for the tool to consider bus contention prevention during the ATPG process.

Example

The following example creates an ATPG constraint and then checks for mutual exclusivity:

add_atpg_constraints 1 435
analyze_atpg_constraints 435 -exclusive

```
// ATPG constraint 435=1 failed mutual exclusivity check (data
                                       in parallel pattern 0).
```

Related Commands

add_atpg_constraints

analyze_bus

Context: dft -edt, patterns -scan

Mode: analysis

Usage

analyze_bus {***gate_id#***... [-Exclusivity | -Prevention | -Zstate]} |
-Drc_check | -ALl | -Auto | -ANAlyze_sequentially

Description

Analyzes the specified bus gates for contention problems.

If the bus passes the analysis, the tool displays a message indicating that it did so. If the analysis aborts, the tool displays a message that identifies the tri-state drivers (TSDs) the tool was analyzing at abort time. If the bus fails the analysis, the tool displays a message that identifies the two offending TSDs (the tri-state drivers capable of being on simultaneously, while driving different values).

Note

After using the analyze_bus command, the set_gate_report Parallel_pattern 0 command may display conflicting values if failures are found. That is, it is possible to have TIE-X gates with a 1/0 as an output. This is due to the analyze_bus command setting values to determine contention states. This analysis continues until a conflict is found.

In the tool, analyze_bus only shows the values that were used by the ATPG, and which the command considers relevant to the bus conflict. As the purpose of the analysis is to determine TSD input combinations that result in bus conflicts, the command does not simulate the output values of the TSD.

Note

With EDT on, Tessent TestKompress support of this command is limited: it will not tell you if a constraint cannot be satisfied with EDT compression. It may also falsely report a constraint can be satisfied.

The commands “set_contention_check On -Atpg” and “set_iddq_checks -Bus” both cause ATPG to ensure that every bus is contention free during deterministic test generation. Sometimes, this requirement cannot be met for many or all of the faults targeted by ATPG, preventing you from obtaining adequate fault coverage. When this happens, the analyze_bus command determines which bus or buses cannot be made contention free, so that you can investigate the circuit around this bus to find out what is preventing contention- free tests.

When you issue this command, you must either specify a *gate_id#* value or one of the global switches (-Drc_check or -All).

Arguments

- ***gate_id#*** -Exclusivity | -Prevention | -Zstate

  A repeatable integer with an optional switch that specifies the identification number of the bus gate and the type of analysis you want the tool to perform.

  The available switch choices are as follows:

  -Exclusivity — An optional switch that specifies for the tool to analyze the bus gate to see if it has mutual exclusivity. Mutual exclusivity means that only one driver can simultaneously force a strong signal onto the bus. Exclusivity is the default behavior when you specify a *gate_id#* value without a corresponding switch.

  -Prevention — An optional switch that specifies for the tool to analyze the bus gate for its ability to attain a state of non-contention.

  -Zstate — An optional switch that specifies for the tool to analyze the bus gate for its ability to attain a high-impedance (Z) state.

- **-Drc_check**

  A switch that specifies for the tool to run the design rule check process again to categorize all buses and display the results. This is useful if you are changing constraints or the abort limit in an attempt to pass bus checks rather than abort.

- **-ALl**

  A switch that specifies for the tool to use the more extensive ATPG process to place all the fail and abort buses in a noncontentious state. The internal simulation data for this pattern is available in parallel pattern 0.

- **-AUto**

  A switch that automatically tries to locate the bus that cannot be made contention free. The analysis checks to see if any single bus cannot be made contention free. Each bus that cannot be made contention free (given the current abort limit and other restrictions) is reported to the user. Sometimes, each bus can be satisfied by itself, but some set of buses cannot all be satisfied. In this case, -Auto switch proceeds to a second analysis where it creates a minimized set of buses that can't be satisfied. The final, reduced set of buses, which cannot all be made contention free, is reported.

- **-ANAlyze_sequentially**

  A switch that specifies to perform a sequential analysis to find bus contention problems. For each clock defined using the add_clocks command, the sequential analysis applies a 1-cycle test, then a 2-cycle test, and so on, up to the reporting depths for which the tests fail. It then analyzes and lists the specific buses causing the failures at those depths.

Note

The same sequential analysis is performed automatically by the analyze_restrictions command if that command finds bus contention is the problem preventing success.

Example 1

The following example analyzes a bus that failed the regular bus contention checking:

set_system_mode analysis
analyze_bus 493

Example 2

The following example displays the current categorization of bus gates, and then performs the prevention check on a specific bus gate:

set_system_mode analysis
analyze_bus -drc_check

```
// ATPG bus checking results: pass=1, bidi=1, fail=0, abort=0,
                                        CPU time=0.00.
```

analyze_bus 495 -prevention

```
// Controllability justification was successful (data
                     accessible using parallel_pattern 0).
// Pattern type: Basic_scan
```

Example 3

The following example analyzes a bus that failed the regular bus contention checking. Notice the input values of gates 7 & 8 (the two TSDs) show that ATPG has correctly illustrated a conflict condition:

```
//  Warning: BUS gate /Y (9) has possible contention
      on drivers 7 and 8. (E10-1)
```

analyze_bus 9

```
//  ATPG bus checking performed on /Y (9) for 2 bused TSDs.
//  Failure occurred while checking TSDs 7 and 8
      (data in parallel_pattern 0).
```

set_gate_report parallel 0
report_gates 9

```
//  /Y (9)  BUS
//      "I0"   I  (X)  7-/tri01/Y
//      "I1"   I  (X)  8-/tri02/Y
//      "OUT"  O  (X)  10-/Y
```

report_gates 7

```
//  tri01 (7)  TSD
//      E      I  (1)  3-/E
//      "D"    I  (1)  5-
//      Y      O  (X)  9-
```

report_gates 8

```
//  tri02 (8)  TSD
//      E      I  (1)  4-/E1
//      "D"    I  (0)  6-
//      Y      O  (X)  9-
```

[-COVerage_effort {Low | High}]
[-NO_REDundancy_analysis]
[-NO_TERMINATE_ineffective_atpg]
[-PATterns_per_pass *integer*]

Emulating a virtual modular EDT configuration

analyze_compression [-Preserve_faults_from_analysis]
[-COMPACTOR_type Xpress | Basic]
[-SHift_power_control [-SWitching_threshold_percentage *int*]]
[-SEParate_control_data_channels]
{-Edt_block *block1_name* [-CHAINs *int*] { [-CHANNELs *int*]
[-INPut_channels *int* -OUtput_channels *int*]}}
[{-Edt_block *block2_name* [-CHAINs *int*] { [-CHANNELs *int*] |
[-INPut_channels *int* -OUtput_channels *int*]}} ...]
{[-SHARE_data_channels [{*block3_name block4_name* ...}]
[-DATA_and_control_channels [*int*]]]} ...
[-OVerride_user_settings | -NO_AUto]
[-COMpaction_effort {Low | High | Maximum | integer}] [-NO_Analyze]
[-COVerage_effort { Low | High }]
[-NO_REDundancy_analysis]
[-NO_TERMINATE_ineffective_atpg]
[-PATterns_per_pass integer]

Description

Analyzes the compression for an application in two steps.

The two steps are as follows:

1. Analyzes a scan-inserted design and returns a range of maximum chain:channel ratios where the test coverage begins to decline.
2. Emulates a hardware configuration for a specified chain:channel ratio, generates temporary test patterns, and returns test data statistics for the compression configuration.

The analyze_compression command uses the fault model type specified by the set_fault_type command. If no fault model type is specified, the tool uses the "stuck" fault model by default. The analyze_compression command uses the current fault population. If no faults are added, the tool operates on all faults or a subset of sampled faults that are determined by the fault sampling rate specified by the "set_fault_sampling <rate>" command.

To enable N-detection during analysis, you must first issue the set_multiple_detection command. After enabling N-detection, you can run the analyze_compression command with the -Preserve_faults_from_analysis switch and the tool preserves the N-detection information for all the detected faults; if you do not specify the -Preserve_faults_from_analysis switch, the tool restores the N-detection information for all detected faults to the states prior to the execution of the analyze_compression command. For an example of enabling N-detection, see Example 16.

Note

During emulation, if the emulated EDT block has the same name as the original one, the tool preserves all the scan cells in the original EDT block; if you specify new EDT block names, the tool tries to allocate all scan cells into the new EDT blocks to get balanced scan chains. You cannot mix the names of the original EDT blocks with the names of the newly emulated EDT blocks. This is illustrated in Example 17.

For more information, see "Analyzing Compression" in the *Tessent TestKompress User's Manual*.

Note

When you perform compression analysis, the final order of scan cells in each scan chain in the design is not known. The order of the scan cells used as deterministic bits in the test cube impacts ATPG results. If many of the deterministic bits are clustered in consecutive cycles, more EDT_ABORT faults may appear because the clustered deterministic bits may not be compressed. When this occurs, ATPG test coverage may drop.

During compression analysis, TestKompress assumes the scan chains are organized in a balanced way based on an existing scan cell ordering. However, in the real design, scan cells may be in an arbitrary position depending on which scan stitching tool was used. If the clustering of deterministic bits occurs during compression analysis but not in the real design or if the clustering occurs in the real design but not in compression analysis, a discrepancy in the ATPG results may occur.

Arguments

- -Preserve_faults_from_analysis

  An optional switch that preserves the fault status at the end of the analyze_compression operation based on the APTG run of the command even though no patterns are stored. By default, without the -Preserve_faults_from_analysis switch, the fault status at the end of the analyze_compression operation is returned to its status prior to the execution of the command. This switch can be used to experiment with analyzing faults remaining after an analysis run.

  If the -Preserve_faults_from_analysis switch is specified, the tool preserves the N-detection information for all the detected faults during the analyze_compression operation.

Note

When you specify this option, if there are already internal patterns generated by a previous create_patterns command, the tool deletes all internal patterns and issues a warning stating that the previously generated patterns are deleted because they will be inconsistent with the fault population.

- -OVerride_user_settings

  For information about this switch, see the create_patterns command.

- -NO_AUto

  For information about this switch, see the create_patterns command.

- -Compaction_effort {Low | High | Maximum | integer}

  For information about this switch, see the create_patterns command.

- -NO_Analyze

  For information about this switch, see the create_patterns command.

- -COVerage_effort { Low | High }

  For information about this switch, see the create_patterns command.

- -NO_REDundancy_analysis

  For information about this switch, see the create_patterns command.

- -NO_TERMINATE_ineffective_atpg

  For information about this switch, see the create_patterns command.

- -PATterns_per_pass integer

  For information about this switch, see the create_patterns command.

- -COMPACTOR_type Xpress | Basic

  An optional switch that specifies the compactor to use for the analysis. By default, the Xpress compactor is used. The specified compactor is applied to all blocks in a block-level

application. This switch cannot be specified more than once; otherwise, an error message is generated.

- -SHift_power_control [-SWitching_threshold_percentage *int*]

  An optional switch and switch-integer pair that specifies low-power usage for the analysis. You must specify the -Channel option when using this -Shift_power_control option.

  If low-power usage is specified, the tool uses the specified low-power controller for all blocks. If no low-power usage is specified, then no low-power is used. This switch cannot be specified more than once; otherwise, an error message is generated.

  If you do not specify the -switching_threshold_percentage option with the -shift_power_control switch, the default is set to 15%.

  The specified low-power usage applies to all blocks in a block-level application.

- -SEParate_control_data_channels

  An optional switch that, if used, tells the tool to separate control and data channels for all EDT blocks during emulation, regardless of whether channel sharing is used. If this switch is not used, the tool does not separate control and data channels for all EDT blocks unless the block is in a channel sharing group specified with the -SHARE_data_channels switch.

- {-Edt_block *block1_name*} ...

  An optional, repeatable, switch and string pair that specifies the name of a design block containing compression logic (compression block). This option specifies multiple compression blocks for the analysis of a block-level architecture design.

  If you only specify one compression block, the design is treated as a chip-level architecture for analysis.

  Chain and/or channel specifications must be defined for each block individually.

  If you do not specify any compression blocks for a block-level design, the design is analyzed with the configurations defined in the design.

  Only the associated scan cells are used to analyze existing compression blocks. If you do not specify any scan channels for existing blocks, the tool uses those specified in the design.

  If you specify any new compression blocks, the tool completely ignores the scan chain and channel configurations defined in the design. For the analysis, the tool distributes the scan cells across all specified blocks in a way that balances the scan chain length for all blocks. In this case, you must specify both chains and channels for each block. You cannot define both new and existing compression blocks in one design.

- -CHAINs *int*

  An optional switch and integer pair that specifies how many scan chains to use when emulating a chain:channel ratio for test data volume and fault coverage analysis. If no scan chains are specified, the scan chains defined in the design are used.

- [-CHANNELs *int*] | [{-INPut_channels *int*}{-OUtput_channels*int*}]

  An optional switch and integer pair or set of switch and integer pairs that specifies the channels to use when emulating a chain:channel ratio for test data volume and fault coverage analysis. Channels must be specified when analyzing a design without compression logic inserted.

  If no channels are specified for a design with compression logic inserted, the following scenarios apply:

  - **Block-level architecture** — The sum of the channels defined for each block is used, and the design is emulated as a single compression block.
  - **Chip-level architecture** — The channels defined by the existing compression logic are used.

  Use the -input_channels/-output channels arguments to specify an asymmetrical channel configuration. These arguments must be used in pairs.

- {[-SHARE_data_channels [{*block3_name block4_name* ...}] [-DATA_and_control_channels [*int*]]]} ...

  An optional argument used to construct one or more channel sharing groups such that the EDT blocks in each channel sharing group share data input channels with each block having individual control channels such that the total number of input channels used in this group equals the input channel number specified by -DATA_and_control_channels. The tool calculates the minimum number of input channels based on the channel sharing groups you define with this argument.

The block_name parameters are the names of the blocks defined to be in the channel sharing group.

The following rules apply to the creation of channel sharing groups:

- If no block_name parameters are specified, the design must already have two or more EDT blocks; otherwise, the tool generates an error.
- If no block_name parameters are specified, all blocks share the data channels; in this case, only one channel sharing group is allowed.
- If block_name parameters are specified, each channel sharing group must have a minimum of two blocks defined; otherwise, the tool generates an error.
- An EDT block can only be defined in one channel sharing group. Note, an EDT block does not have to be defined in any channel sharing group.
- If a block is defined in a channel sharing group, the set_edt_options "-separate_control_data on" switch is automatically set. In this case, the tool calculates the number of control channels that are needed for the block by determining the number of control bits and the length of data channels. The total input channel count for each block, specified by either the analyze_compression "-channels" or "-input_channels"

switches, must be greater than or equal to the number of control channels plus 1. This means the block must have at least one data channel.

- The specified input pin count (N) for each channel sharing group must be greater than or equal to the sum of the #control channels on each block in the group plus 1.That is, at least one pin must be shared by the data channels of the EDT blocks in one channel sharing group.
- The number of input data pins available to be shared in the group cannot be greater than or equal to the sum of all data channels of all blocks in the group.
- The number of input data pins available to be shared in this group must be greater than or equal to the maximum number of data input channels of all EDT blocks in the group.

Example 1

The following example analyzes a design and returns the upper range of chain:channel ratios:

analyze_compression

```
// For stuck-at faults
//
//  Chain:Channel Ratio  Predicted Fault Coverage Drop
//  -------------------  ------------------------------
//  153                  negligible fault coverage drop
//  154                  0.01 % - 0.05 % drop
//  160                  0.10 %
//  168                  0.15 %
//  171                  0.20 %
…
//  CPU time is 155 seconds.
```

Example 2

The following example emulates compression logic with 800 scan chains and 8 scan channels, generates test patterns, and displays test pattern statistics for a chip-level architecture:

set_fault_sampling 1
analyze_compression -chains 800 -channels 8

```

//  total                 8464    8464                  4536704   (4.5M)
//
```

Example 4

In the following example, a fault model type is not specified. By default, the stuck-at fault model type is used.

analyze_compression -chain 100 -channel 2

```
// ************************************
// * Run ATPG for stuck-at faults.
// ************************************
```

Example 5

In the following example, the -Preserve_faults_from_analysis switch is used to update the fault detection status based on the ATPG results of the analyze_compression command.

analyze_compression -chain 100 -channel 2 -Preserve_faults_from_analysis

```
// ************************************
// * Run ATPG for stuck-at faults.
// ************************************

Note: Fault detection status will be updated based on the ATPG results of
analyze_compression even though no patterns are stored.
```

Example 6

In the following example, the set_fault_type command is used to specify the fault model type to be used by the analyze_compression command.

```
set_fault_type transition
analyze_compression -chain 100 -channel 2
```

```
// ************************************
// * Run ATPG for transition faults.
// ************************************
```

Example 7

In the following example, the set_fault_type command is used to specify that a user-defined fault model type is to be used by the analyze_compression command.

```
set_fault _type UDFM
read_fault_sites ../fault/sampled.udfm
analyze_compression -chain 100 -channel 2
```

```
// ************************************
// * Run ATPG for UDFM faults.
// ************************************
```

Example 8

In the following example, the Xpress compactor type is specified for a single EDT block.

```
analyze_compression -compactor_type xpress -chain 100 -channel 2
```

Example 9

In the following example, both EDT blocks are emulated with the Xpress compactor.

```
analyze_compression -compactor_type xpress \
        -edt_block blk1 -chain 100 -channel 2 \
        -edt_block blk2 -chain 200 -channel 2
```

Example 10

In the following example, both EDT blocks are emulated with the Basic compactor.

```
analyze_compression
        -edt_block blk1 -compactor_type basic -chain 100 -channel 2 \
        -edt_block blk2 -chain 200 -channel 2
```

Example 11

In the following example, only one EDT block is emulated with the low-power controller.

```
analyze_compression -shift_power_control -switching_threshold_percentage 20 \
        -chain 100 -channel 2
```

Example 12

In the following example, the low-power controller is used for both EDT blocks. The switching_threshold_percentage switch is set to 20%.

```
analyze_compression -shift_power_control -switching_threshold_percentage 20 \
        -edt_block blk1 -chain 100 -channel 2 \
        -edt_block blk2 -chain 200 -channel 2
```

Example 13

In the following example, both EDT blocks are emulated with the same low-power controller.

```
analyze_compression -edt_block blk1
        -shift_power_control -switching_threshold_percentage 20 -chain 100 -channel 2 \
        -edt_block blk2 -chain 200 -channel 2
```

Example 14

In the following example, only one EDT block is emulated with the low-power controller. The switching_threshold_percentage switch is set to 15% by default.

```
analyze_compression -shift_power_control -chain 100 -channel 2
```

Example 15

In the following example, both EDT blocks are emulated with the low-power controller. The switching_threshold_percentage switch is set to 15% by default.

```
analyze_compression -shift_power_control -edt_block blk1 -chain 100 -channel 2 \
        -edt_block blk2 -chain 200 -channel 2
```

Example 16

The following example enables N-detection ATPG during the analyze_compression.

```
set_multiple_detection -guaranteed_atpg_detections 3 -desired_atpg_detections 1
set_fault_sampling 2
analyze_compression -chain 100 -channel 2
```

```
//  ************************************
//  *   Run ATPG for stuck-at faults.
//  ************************************

```

Example 17

The following examples demonstrate how the tool enforces the naming requirements for the emulation step.

Case 1

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \
                    -edt_block block2 -chain10 -channel 1
```

The tool maintains all cells in the original block1 and block2 because they have the same name as the original, but changes the number of scan chains and channels based on the command.

Case 2

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block3 -chain10 -channel 1 \
                    -edt_block block4 -chain10 -channel 1
```

The tool does not maintain all of the cells in the original blocks because the names changed. The tool reallocates cells to make all of the chains in the two blocks as balanced as possible.

Case 3

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \
                    -edt_block block4 -chain10 -channel 1
```

The tool does not allow the mixing of the original names and the newly specified names and generates an error message.

Case 4

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block1 -chain10 -channel 1
```

The tool does not allow this case because it changes two blocks to one block, but still uses the same name as before.

Case 5

The original design has two EDT blocks named block1 and block2.

```
analyze_compression -edt_block block3 -chain10 -channel 1
```

The tool supports this case.

Case 6

The original design has one EDT block named block1.

```
analyze_compression -edt_block block1 -chain10 -channel 1 \
                    -edt_block block2 -chain10 -channel 1
```

The tool does not allow this and displays an error message.

Case 7

The original design has one EDT block named block1.

```
analyze_compression -edt_block block2 -chain10 -channel 1 \
                    -edt_block block3 -chain10 -channel 1
```

The tool supports this case.

Example 18

The following examples demonstrate how the tool supports channel sharing.

Case 1:

The design has one sharing group with 12 input channels shared between all blocks (block1, block2, block3 and block4).

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 6 \
                    -edt_block block4 -chain 200 -channel 2 \
                    -share_data_channels -data_and_control_channels 12
```

Case 2:

The design has two sharing groups. The first group has 6 input channels shared between block1 and block2. The second group has 8 input channels shared between block3 and block4.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 6 \
                    -edt_block block4 -chain 200 -channel 2 \
                    -share_data_channels block1 block2 -data_and_control_channels 6 \
                    -share_data_channels block3 block4 -data_and_control_channels 8
```

Case 3:

The design has one sharing group with 6 input channels shared between block1 and block2, but block3 does not share any inputs with other blocks.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 6 \
                    -share_data_channels block1 block2 -data_and_control_channels 6
```

Case 4:

In this example, a block is included in multiple channel sharing groups:

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 \
                    -channel 6 -share_data_channels block1 block2 \
                       -data_and_control_channels 6\
                    -share_data_channels block1 block3 -data_and_control_channels 8
```

The following error is generated:

```
Error: Block 'block1' is included in multiple channel sharing groups.
```

Case 5:

In this example, a block is added to a channel sharing group but the block does not share input channels with any other blocks in that group.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 6 \
                    -share_data_channels block1 -data_and_control_channels 6 \
                    -share_data_channels block2 block3 -data_and_control_channels 8
```

The following error is generated:

```
Error: Block 'block1' is specified inside a channel sharing group, but
does not share input channels with any other block.
```

Case 6:

In this example, a block is specified inside more than one channel sharing group.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 6 \
                    -share_data_channels block1 block1 -data_and_control_channels 6 \
                    -share_data_channels block2 block3 -data_and_control_channels 8
```

The following error is generated:

```
Error: Block 'block1' is specified multiple times inside a channel sharing
group.
```

Case 7:

This example assumes that each block needs two control channels.

```
analyze compression -edt_block block1 -chain 100 -channel 3 \
                    -edt_block block2 -chain 200 -channel 4 \
                    -edt_block block3 -chain 300 -channel 4 \
                    -share_data_channels -data_and_control_channels 6
```

The following error is generated:

```
Error: Channel sharing group with 'block1' (2 control channel), 'block2'
(2 control channel), and 'block3' (2 control channels) needs at least 7
input channels for channel sharing."
```

Case 8:

This example assumes that block1 has one control and one data channel; block2 has one control channel and two data channels; and block3 has two control channels and two data channels. Because the command specifies to share nine channels, no channels are actually shared.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 3 \
                    -edt_block block3 -chain 300 -channel 4 \
                    -share_data_channels -data_and_control_channels 9
```

The following error is generated:

```
Error: Excessive input channels specified for channel sharing group which
includes 'block1'. This group requires between 6 and 8 input channels.
```

Case 9:

This example assumes that block1 has one control and one data channel; block2 has one control channel and two data channels; and block3 has two control channels and two data channels. The command specifies to share five channels which is not enough.

```
analyze compression -edt_block block1 -chain 100 -channel 2 \
                    -edt_block block2 -chain 200 -channel 3 \
                    -edt_block block3 -chain 300 -channel 4 \
                    -share_data_channels -data_and_control_channels 5
```

The following error is generated:

```
Error: The available input channels (5) specified for the channel sharing
group is not enough to drive the data input channels for block 'block2'
and 'block3'. This group requires between 6 and 8 input channels.
Alternatively, if you want to keep the shared channel count (5), you may
reduce the number of input channels for the following blocks:
'block1' may have up to 2 channels.
'block2' may have up to 2 channels.
'block3' may have up to 3 channels.
```

Case 10:

In this example, channel sharing is specified but neither the total number of input pins nor any channel sharing groups are defined. In this case, the tool defines the channel sharing group to be all EDT blocks and calculates the required number of input channels for those three blocks.

analyze compression -share_data_channels

The following message is generated:

```
// Sharing 8 input channels across block1 block2 block3.
```

Case 11:

In this example, channel sharing is specified and two channel sharing groups are defined. However, the total number of input pins is not specified. In this case, the tool calculates the required number of input channels for each of the two defined channel sharing groups.

```
analyze compression \
                    –edt_block block1 –chain 100 –channel 2 \
                    –edt_block block2 –chain 200 –channel 4 \
                    –edt_block block3 –chain 300 –channel 6 \
                    –edt_block block4 –chain 200 –channel 2 \
                    -share_data_channels block1 block2 \
                    -share_data_channels block3 block4
```

```
// Sharing 8 input channels across block1, block2.
// Sharing 10 input channels across block3, block4.
```

analyze_control_signals

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

analyze_control_signals [-Report_only | -Auto_fix] [-Verbose]

Description

Identifies and optionally defines the primary inputs of control signals.

The analyze_control_signals command identifies each control signal (clocks, set, reset, write-control, read-control, and so on) of every sequential element (DFF, latch, RAM, ROM, etc.) and optionally defines its primary input as a control signal. The purpose of analyzing the control signals is to identify the primary inputs that need to be defined as a clock, read-control, or write-control. This analysis also considers pin constraints, but only traces through simple combinational gates.

If the -Verbose option is specified, the tool issues messages that indicate why certain control signals are not reported. At the end of the analysis, the tool displays statistical information such as the number of primary inputs identified as control signals, their types, and additional information.

If the -Auto_fix option is specified, all identified primary inputs of control signals are automatically defined. For example, when a clock is identified, an implicit add_clocks command is performed to define the primary input. By default, all control signals are only reported.

This command performs the flattening process automatically, if executed prior to performing flattening.

Note

The tool defers to your expert knowledge when you use add_clocks to define a clock; the -Auto_fix option will not alter a clock definition specified by a preceding add_clocks command.

dft -scan Details

Because it is not possible to completely identify all control signals, you should only use the results of this command as a *starting point* in creating a dofile that defines the clock control signals, read and write controls in a design. You should use this dofile when the tool is being used for production scan and test logic insertion. Situations where the tool may not be able to identify particular control signals include the following:

- When the tool is unable to trace or simulate through complex logic, the tool cannot identify a top-level pin as a clock. These cases include clocks driven by PLLs or clock

gaters that require simulating a test setup procedure to obtain a sensitizable path to a top-level pin.

- The tool cannot accurately predict the off-state of a clock by observing the flip-flops it is driving and, therefore, requires the user to verify that the off-state of the clock/set/reset lines is correct.

Because of these types of issues, this command does not identify all clocks, their offstates, or controls signals. In this case, you should explicitly add the unidentified clocks using the add_clocks command.

Arguments

- -Report_only

  An optional literal that specifies to identify control signals only (does not define the primary inputs as control signals). This is the invocation default.

- -Auto_fix

  An optional literal that specifies to define the primary inputs of all identified control signals as control signals. For example, when a clock is identified, an implicit add_clocks command is performed to define the primary input.

- -Verbose

  An optional literal that specifies to display information on control signals (whether they are identified or not, and why) while the analysis is performed.

Example

The following example analyzes the control signals, then only provides a verbose report on the control signals in the design. After examining the transcript, you can then perform another analysis of the control signals to add them.

analyze_control_signals -verbose

```
//  command: analyze_control_signals -reports_only -verbose
-------------------------------------------------------------------------

//  Begin control signals identification analysis.
-------------------------------------------------------------------------
//  Warning: Clock line of '/cc01/tim_cc1/add1/post_latch_29/WRITEB_reg/r/
    (7352)' is uncontrolledat '/IT12 (4)'.
...
...
...
//  Identified 2 clock control primary inputs.
//     /IT23 (5) with off-state = 0.
//     /IT12 (4) with off-state = 0.
//  Identified 0 set control primary inputs.
//  Identified 1 reset control primary inputs.
//     /IRST (1) with off-state = 0.
//  Identified 0 read control primary inputs.
//  Identified 0 write control primary inputs.
-------------------------------------------------------------------------
```

```
//  Total number of internal lines is 105 (35 clocks, 35 sets , 35 resets,
      0 reads, 0 writes).
//  Total number of controlled internal lines is 25 (17 clocks, 0 sets ,
      8 resets, 0 reads, 0 writes).
//  Total number of uncontrolled internal lines is 80 (18 clocks, 35 sets,
      27 resets, 0 reads, 0 writes).
//  Total number of added primary input controls 0 (0 clocks, 0 sets ,
      0 resets, 0 reads, 0 writes).
-----------------------------------------------------------------------
```

analyze_drc_violation

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -ijtag, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Usage

analyze_drc_violation ***rule_id-occurrence#*** [-Display [APpend]]

Description

Generates a schematic in the Debug window of the portion of the design involved with the specified rule violation number.

When you issue the analyze_drc_violation command, the tool includes different simulation data in the netlist depending on the type of rule violation. The tool automatically opens the Debug window of DFTVisualizer if it is not already open, and sets the gate reporting to match the type of rule violation, just as if you had manually issued the set_gate_report command. The gate report setting is shown on the status bar. For some DRC violations (E5 for example), the gate level is automatically set to primitive.

Note that the following DRC errors do not have additional information that can be displayed with DFTVisualizer:

B1—B16
E1, E12, E13
G rules
K rules
P rules
T1, T8—T11, T13—T15, T18—T23
W1—W19, W32, W33

For more information about displaying DRC information, refer to the report_drc_rules command. For information about each DRC, refer to "Design Rule Checking" on page 2135.

Arguments

- ***rule_id-occurrence#***

  A literal and integer argument pair that specifies the exact design rule violation (including the occurrence) that you want to analyze. The tool traces the violation back to the probable cause and then the schematic viewer displays all the gates in that trace. The argument must include the design rules violation ID (*rule_id*), the specific occurrence number of that violation, and the hyphen between them. For example, you can analyze the second occurrence of the C3 rule by specifying C3-2. The tool assigns the occurrences of the rules violations as it encounters them, and you cannot change either the rule identification number or the ordering of the specific violations.

- -Display [APpend]

  A switch and literal pair that specifies to append the schematic to the existing contents of the Debug window instead of replacing the contents. If you specify the -Display switch without the Append switch, the existing schematic is deleted and new data is shown in the Debug window.

Examples

The following example defines the off-state of a clock incorrectly, causing a C2 rule violation. When a rule violation occurs, you can use the Debug window to analyze the probable cause of the error.

With this example, the Debug window displays the sequential element associated with the clk input, along with a backward trace through the gates and nets to the associated primary input.

add_clocks 0 clk
set_system_mode analysis

```
...
//  ---------------------------------------------------------
//  Begin scan clock rules checking.
//  ---------------------------------------------------------
//  1 scan clock/set/reset lines have been identified.
//  All scan clocks successfully passed off-state check.
//  Error: Clock /CLK cannot capture data with other clocks off. (C2-1)
```

analyze_fault

Context: dft -edt, patterns -scan

Mode: analysis

Usage

Path Delay Usage: analyze_fault path_name **{-Rise | -Fall}** [-Observe gate_ID#] [-Auto] [-Display [APpend]]

Stuck/Transition Usage: analyze_fault ***pin_pathname*** **{-Stuck_at {0 | 1} | -Rise | -Fall}** [-Observe *gate_id#*] [-Boundary] [-AUto] [-Continue] [-Display [APpend]]

Description

Performs an analysis to identify why a fault is not detected and optionally displays the relevant circuitry in DFTVisualizer.

The analyze_fault command performs an analysis to identify why the fault that you specify was not detected. You can use the -Observe switch to specify the observe point for the sensitization analysis.

If you are using DFTVisualizer, you can specify the -Display switch to graphically display the relevant circuitry for any fault detection. This may assist you in identifying either why a fault wasn't detected or how a fault was detected.

The fault analysis performed by the analyze_fault command consists of the following actions:

1. A message is given if the selected fault has been nofaulted.
2. A message is given that will identify if the fault is in the current fault list. If the fault is in the current fault list and the fault is the representative member, its fault classification is displayed.
3. If the fault was not identified as included in the active fault list, the basic fault analysis is performed that determines if the fault can be classified as unused, tied, blocked, or detected by implication.
4. If the fault category is detected by simulation, detected by implication, or unused, a message is given and the analysis is terminated. You can override the termination by using the -Continue switch.
5. If the fault category is tied, all sources of the tied condition are identified and the analysis is terminated.
6. If the fault category is blocked, all blockage points (100 maximum) are identified. For each blockage point, all sources of the tied conditions causing the blockage are identified. The analysis then terminates.
7. The states that result from all constrained pins and stable non-scan cells are calculated.

8. If the fault site is now prevented from attaining the necessary state, a message is given indicating the fault is tied by constrained logic, all sources of the tied condition are identified, and the analysis then terminates.
9. An analysis is made to identify all blockage points (100 maximum) and all potential detection points (25 maximum).
10. If there are no potential detection points, the blockage points are identified and for those points blocked by tied logic, all sources of the tied condition are identified. The analysis then terminates.
11. If there were potential detection points, the detection points are identified (25 maximum).
12. A controllability test generation is performed to determine if the fault site can be controlled. If successful, the test generation values are displayed using parallel_pattern 0. If unsuccessful, the analysis then terminates.
13. If an observe point is not selected, a complete test generation is attempted where the fault is sensitized from the fault site to any unblocked point. Potential problem points in any sensitization path are identified. The points will include tri-state driver enable lines, transparent latch data lines, clock_pos, wire gates, latch and flip-flop set/reset/clock lines, RAM write/read/address/data lines, and ROM read/address lines. If the test generation is successful, the test generation values are displayed using parallel_pattern 1.
14. If an observe point is selected, the fault is sensitized from the fault site to the observe point. Potential problem points in the sensitization path are identified. If the sensitization is successful, the test generation values are displayed using parallel_pattern 1.

Note

Only stuck-at, path delay and transition fault types can be analyzed using the analyze_fault command.

When the fault type is path delay, the analyze_fault command performs an unsensitizable path analysis when the ATPG run is unable to create a test pattern. If the analysis finds that some segment of the path is unsensitizable, it attempts to find a minimum number of gates in the path which are required to prove the path unsensitizable.

For example:

analyze_fault path37 -s 0

produces the following report:

```
//  ---------------------------------------------------------
//  Path delay fault analysis for path37 slow to rise on
// launch point = 22032, capture point = 167521
//  ----------------------------------------------------------
//  Path delay test generation not successful for capture point = 167521
//  due to atpg_untestable.
//  Begin unsensitizable path analysis for path=path37
//  Cycle=0 path sensitisation check failed status=redundant
//  Simultaneous sensitisation of 2 path segments cannot be achieved
//  (status=redundant).
//  These are:
//      OR   145279 (I1) + ;
//      ...
//      AND  150252 (I1) + ;
//  Path is a static unsensitizable path. Robust detection will be
//  impossible.
```

The analyze_fault report shows that it is impossible to use both input 1 (the second input, inputs are numbered starting at 0) of the OR gate 145279 while at the same time using input 1 of the AND gate 150252. The ellipsis (...) indicates that there are other gates in the path between the reported gates which are not relevant to the unsensitizable path problem.

The delete_fault_sites -Unsensitizable_paths command lets you delete proven unsensitizable paths.

When the fault type is transition, the analyze_fault command performs the following analysis steps:

1. The controllability of logic value 0 and 1 at the fault site is analyzed.

   If the analysis succeeds, the fault site is controllable. You can access the analysis results by setting the gate report type to be parallel pattern 0(2) to set logic value 1(0) at the fault site for a slow-to-rise fault, or logic value 0(1) at the fault site for slow-to-fall fault.

   If the tool aborts this step or it otherwise fails, the fault cannot be detected due to a lack of controllability at the fault site. The tool then terminates the analysis unless you force it to continue.

2. The ability to launch a slow-to-rise (0 -> 1) or slow-to-fall (1 -> 0) transition at the fault site is analyzed.

   If the analysis succeeds, the desired transition can be created at the fault site. You can access the analysis results by setting the gate report type to be parallel pattern 3.

   If the tool aborts this step or it otherwise fails, the fault cannot be detected because a transition cannot be launched at the fault site. The tool terminates the analysis unless you force it to continue.

3. The tool attempts to generate a test pattern for the transition fault being analyzed.

If successful, a test pattern exists to detect the fault. You can access the analysis results by setting the gate report type to be parallel pattern 1 and the analysis process terminates.

If the tool aborts this step or it otherwise fails, the tool will proceed to the next step.

4. The tool attempts to generate a test pattern for a stuck-at fault at the same fault site.

   If successful, there exists a sensitive path from the fault site to an observation point. The reason for aborting or failing to generate the test pattern for the original transition fault is that launching a transition at the fault site may block the fault propagation path. You can access the analysis results for the stuck-at fault by setting the gate report type to be parallel pattern 4.

Arguments

- ***pin_pathname***

  A required string that specifies the pin pathname of the fault where you want to perform the analysis.

- **-Stuck_at 0 | 1**

  A switch and literal pair that specifies the stuck-at fault value that you want to analyze. The stuck-at values are as follows:

  0 — A literal that specifies that the tool analyze the *pin_pathname* for a “stuck-at-0” fault.

  1 — A literal that specifies that the tool analyze the *pin_pathname* for a “stuck-at-1” fault.

- **-Rise**

  A switch that specifies a slow-to-rise transition fault.

- **-Fall**

  A switch that specifies a slow-to-fall transition fault.

- -Observe *gate_id#*

  An optional switch and integer pair that specifies the observe point for the sensitization analysis.

  gate_id# — An integer that specifies a gate identification number whose location you want to use as the observe point for the sensitization analysis.

- -Boundary

  An optional switch that specifies to display the boundary faults when analyzing an ATPG untestable, tied, blocked, or redundant fault.

- -AUto

  An optional switch, applicable only to path delay faults, that automatically determines how far along the path the tool can successfully propagate a path delay fault.

- -Continue

  An optional switch that forces the tool to complete the analysis of faults that have already been detected by the pattern set. This lets you inspect the generated pattern by using the report_faults command.

  If you do not specify this switch and the tool detects the fault category by simulation, by implication, or as unused, then the tool displays a message and terminates the analysis.

- -Display [APpend]

  An optional switch and literal pair that specifies for the tool to create a gate list relevant to the fault being analyzed and, if DFTVisualizer is open, to automatically update the schematic in the Debug window with the information; if the Append switch is specified the schematic is appended to the existing contents of the Debug window instead of replacing the contents.

  The schematic view contains annotations for the following cases as required:

  - Successful ATPG — All gates that sensitize the fault effects to an observable point are added to the gate list. The pins on these gates are annotated with the simulated value that results from the pattern that was created.
  - Uncontrollable Fault Site due to Forbidden Conditions — All gates that prevent the fault site from attaining the required state are added to the gate list. The pins on these gates are annotated with the constrain_value data.
  - Blocked Fault Site due to Forbidden Conditions — All gates that sensitize the fault effects to the blockage point and all gates that prevent the blockage points from attaining the necessary values are added to the gate list. The pins on these gates are annotated with the constrain_value data.

Example

The following example performs test pattern generation, then performs an analysis to determine why the tool did not detect a stuck-at-1 fault at pin /G:

set_system_mode analysis
create_patterns
report test data -class au

```
//  fault analysis summary of 3 faults
//  number faults blocked by constraints = 3
//  number faults connected to nonscan_latch = 3
//  number faults connected to clock/set/reset = 3
//  number faults unclassified = 0
```

report_faults -class au

```
type   code   pin_pathname
----   ----   ------------------------------------
  1     AU    /lat1/DL2/CLK1
  1     AU    /G
  1     AU    /lat2/DL2/CLK1
```

analyze_fault /G -stuck_at 1

```
// ---------------------------------------------------------
// Fault analysis for /G (4) output G stuck at 1
// ---------------------------------------------------------
// Current fault classification = AU (atpg_untestable)
// 1 potential observation points were identified:
//    Potential observe point: PO /V_VOUT (1968).
// Controllability justification was successful
      (data accessible using parallel_pattern 0).
// Pattern type: Basic_scan.
// The following potential detection path problems were id'd:
// Potential detection paths propagated through 1
//    transparent cell clock lines.
//  Test generation performed using all observable detection
//    points.
//  Fault was not successfully detected - fault status =
//    atpg_untestable.
```

analyze_graybox

Context: patterns -scan

Mode: analysis

Usage

analyze_graybox [–no_reset] [–preserve_instances *instance_objects*]
[-max_sequential_levels {*number* | unlimited}] [-collect_reporting_data]

Description

Identifies the instances and nets to be included in the graybox netlist by automatically setting their in_graybox attributes to “true”. Subsequently, a “write_design -graybox” command writes out the graybox netlist for the marked instances and nets.

Before issuing the analyze_graybox command, you must place the design in external mode. That is, the output wrapper chains should be set up in non-capture mode, whereas the input wrapper chains are set up in both capture and shift (or hold or rotate) modes. At the end of the analysis, a summary of the identified instances displays in the session transcript.

The graybox analysis performs the identification by tracing backward from all primary output pins, wrapper chain sequential cell input pins and specified preserve instance input pins. In general, the backward tracing used by the graybox analysis considers a path sensitization that is based on the state-stability values obtained by simulating the pin constraints and test-setup procedures provided for the external test mode. However, a pure structural tracing method is used when tracing backward from preserve instance input pins.

You should exclude the scan-out pins of the core chains from the backward tracing to prevent marking internal (core) logic for graybox. You accomplish this by setting the ignore_for_graybox attribute of the scan-out pins to “true” using the set_attribute_value command.

The -preserve_instances option can be used to include arbitrary instances (the instantiations of modules or the instantiations of library models) in the graybox logic. The tool bypasses the graybox analysis within specified preserve module instances and automatically includes all of their sub-instances and nets in graybox. This allows you to overcome the limitations that the sensitized path based backward tracing imposes, such as not allowing complex test-setup procedures that initialize non-scan cells in clocks paths, limiting the sequential depth, etc.

One typical scenario to use the -preserve_instances option is when the design includes EDT logic driving the scan I/O pins of the wrapper chains. The entire EDT block can be specified as a preserve instance if graybox analysis cannot identify the EDT logic due to setup restrictions. To also include any depth of sequential pipeline stages on EDT channel pins, EDT Finder can be used along with graybox analysis. EDT Finder then identifies the EDT logic with the pipeline stages and automatically adds them as preserve instances for graybox analysis.

Arbitrary instances and arbitrary nets in the design can be marked for graybox netlist generation by manually setting their in_graybox attributes to “true” using the set_attribute_value

command. These attributes are reset to “false” by the analyze_graybox command unless you specify the –no_reset switch.

Note

Manually marking instances and nets for graybox netlist is not recommended because the tool does not automatically mark the nets and instances between such instances and the instances identified through the graybox analysis. Besides, the manual marking of instances and nets should be performed hierarchically to cover the parent instances and nets in order to properly synthesize them in the generated graybox netlist.

Currently, only Mux-DFF scan architecture is supported with the graybox functionality.

For more information about graybox concepts and procedures, refer to “Graybox Overview” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- –no_reset

  An optional switch that specifies not to reset the previously set in_graybox attributes of all design instances, and set additional ones identified by the graybox analysis. By default, the tool resets all in_graybox attributes when the command is issued without this switch.

- –preserve_instances *instance_objects*

  An optional switch with a Tcl object list that automatically includes instances in the graybox netlist without having to deploy the graybox analysis tracing routines on these instances and the sub-instances contained within. The connections to and from the preserved instances are still determined by the analysis to include in the graybox netlist. You can also declare the specified instance objects as blackbox module instances before the analysis.

- -max_sequential_levels {*number* | unlimited}

  An optional switch and integer or literal pair that limits the number of sequential levels (flip-flops) traced backward from a trace origin (a PO, a wrapper cell input pin, or a “preserve instance” input pin). When the sequential levels limit is reached, the tool stops collecting the graybox logic for the trace origin. Sequential cells that are part of wrapper chains or initialized to constant values (Tie-0/1) with an active set/reset pin are not counted as sequential levels when tracing backward. The “number” argument can accept a value of 1 or greater, where 2 is the default value when this switch is not specified with the command. The “unlimited” argument specifies to not limit the number of sequential levels during backtracing.

- -collect_reporting_data

  An optional switch that specifies to count the number of leaf instances (library model instances at design level) that are marked for each backward tracing origin, such as a PO, a wrapper cell input pin, or a “preserve instance” input pin (all input pins combined). This switch is required if you want to use the report_graybox_statistics command to report the

collected data. Note that collecting reporting data requires additional netlist tracing and could impact analysis execution performance.

Example

The following command performs graybox analysis on the current design. The module instance "tap_ctrl_ins" and all sub-instances within are marked for graybox logic without going through the graybox analysis.

```
analyze_graybox -preserve_instances tap_ctrl_ins -collect_reporting_data
report_graybox_statistics -top 10
```

Related Commands

report_graybox_statistics
set_attribute_value
write_design

analyze_restrictions

Context: dft -edt, patterns -scan

Mode: analysis

Usage

All Fault Types Except IDDQ Faults Usage:
analyze_restrictions [-Auto | -OLD] [-COnflict_source_analysis]

IDDQ Faults Usage:
analyze_restrictions [-INT_float_auto_except]

Description

Performs an analysis to automatically determine sources of the problem from a failed ATPG run.

The analyze_restrictions command reports the ATPG restrictions that caused a failed ATPG run. If you issue the analyze_restrictions command without an argument, the default is -Auto. The analysis may be lengthy depending on the number of restrictions. You can stop the analysis at any time by pressing Ctrl-C.

Arguments

- -Auto

  An optional switch that automatically performs the following step-by-step analysis:

  - **Step 1** — The tool identifies the type of constraints that failed the analysis.
  - **Step 2** — The tool analyzes the problem constraint types and finds the minimum constraints that prevent the tool from passing the analysis.
  - **Step 3** — Optional. The tool performs a detailed analysis of each constraint identified in Step 2. You perform this detailed analysis by using the -COnflict_source_analysis switch in conjunction with the -Auto switch.

  The set of constraints that conflict with the constraint are reported. The tool analyzes the constraints in the following order:

  1. dynamic ATPG constraints
  2. dynamic cell constraints
  3. static ATPG constraints
  4. static cell constraints
  5. named capture procedure
  6. bus floating checking
  7. bus contention (with the specified driver restriction)

8. port contention

- -OLD

  An optional switch that performs the analysis using functionality from releases prior to the 2007_2 release. It reports the ATPG restrictions that caused a failed ATPG run by category. These categories include ATPG constraints, IDDQ constraints, IDDQ checks, and contention checks. If the analysis determines bus contention is preventing success, a sequential analysis is performed. For more information on sequential analysis, see the -analyze_sequentially option of the analyze_bus command.

- -COnflict_source_analysis

  An optional switch that performs a detailed analysis (Step 3) of each constraint identified in Step 2 in the -Auto switch description. This option can increase the tool's runtime under certain circumstances.

- -INT_float_auto_except

  An optional switch that creates Iddq exceptions automatically for the "-int_float" Iddq check failure sites found during the analysis. Iddq exceptions are defined for failures that are the result of "-int_float" Iddq checks previously specified with the set_iddq_checks command. You can report the automatically added exceptions with the report_iddq_exceptions command or use the delete_iddq_exceptions command to remove unwanted exceptions.

Example 1

The following example analyzes a failed ATPG run in which a user-specified ATPG constraint is conflicting with a cell constraint and causes the ATPG to fail test generation.

create_patterns

```
//  Error: Current restrictions can NOT be simultaneously satisfied with
//  ANY abort limit. Status=atpg_untestable.
//  Halting run.  Suggest analyze_restrictions.
//  You can specify the -NOAnalyze option in command "create_patterns"
//  to force the run, but coverage will probably be low.
```

analyze_restrictions

```
//   -------------------------------------
//  | Step-1  Global constraint analysis |
//   -------------------------------------
//    Order-1: dynamic ATPG constraints, analysis=to_be_analyzed
//   ----------------------------------------------------
//  | Step-2  Identifying minimum conflicting constraint |
//   ----------------------------------------------------
//  Following atpg constraints conflict with the rest of constriants:
//    atpg constraint: 1 dynamic  /FF3/Q (10)
//  You can use -conflict_source_analysis switch to analyze which
//  constraints conflict with the above constraints.
```

To perform detailed analysis of the conflict, then issue the analyze_restrictions command with the optional -conflict_source_analysis switch:

analyze_restrictions -conflict_source_analysis

```
//   -----------------------------------
//  | Step-1  Global constraint analysis |
//   -----------------------------------
//    Order-1: dynamic ATPG constraints, analysis=to_be_analyzed
//   ----------------------------------------------------
//  | Step-2  Identifying minimum conflicting constraint |
//   ----------------------------------------------------
//  Following atpg constraints conflict with the rest of constriants:
//    atpg constraint: 1 dynamic  /FF3/Q (10)
//   ------------------------------------------------------------------
//  | Step-3  Identifying conflict source of first problem constraint |
//   ------------------------------------------------------------------
//  Following constraint conflicts with problem constraint #1:
//    atpg constraint: 1 dynamic  /FF1/Q (8)
```

Example 2

The following IDDQ example analyzes a failed ATPG run, displays the results of the analysis, and automatically adds an Iddq exception for each ZVAL gate that failed in an “-int_float” Iddq check. Only part of the report, about Iddq failures, is shown.

analyze_restrictions -int_float_auto_except

```
...
//  With Iddq constraints and Iddq checks removed, PASSES ability to
satisfy restrictions.
//  Problem is with Iddq specific restrictions. Analyzing further to find
problems.
//  With Iddq constraints removed, and all Set Iddq Check options removed
except -intfloat, FAILS.
//  Must fix -intfloat option problems to generate ANY iddq test given
current restrictions & circuit.
//  Will attempt to locate and report specific -int_float violators.
//  No single bus is constrained to Z (or already Z).  Will analyze
further.
//  The following ZVAL gates cause -int_float to fail by themselves.
//    ZVAL gate /cpu/alu/U2392/ (54417).  ABORTed.
//    ZVAL gate /cpu/alu/U4177/ (63712).  ABORTed.
//  Will add_iddq_exceptions for -int_float failure sites.
...
```

analyze_simulation_mismatches

Context: patterns -scan

Mode: analysis

Usage

analyze_simulation_mismatches {**-AUto**
| {**-FAilure_file** ***failure_file*** [**-VCD_file** ***vcd_filename***]}
| {**-MISmatches** ***mismatch_bit***...} | ***Verilog_testbench_pathname*** }
[-Internal_patterns | -External_patterns]
{[-SImulation_script ***simulator_invoke_script***] | [-MAnual]}
[-SCan_test | -CHain_test | -ALl_test] [-HOST ***server_name***] [-Lib ***lib_name***]
[-TEstbench_for_vcd ***new_filename*** [-REplace]] [-SHift_check { ON | OFF }] [-VErbose]

Description

Analyzes simulation mismatches that occur between test patterns and a simulation performed by a specified external timing simulator.

By default, the simulation VCD file, test patterns, and design data are all analyzed and the mismatch sources are identified. Once the analysis is complete, you can use DFTVisualizer to graphically display the overlapping data and pinpoint the source of each mismatch.

Refer to "Analyzing Simulation Mismatches" in the *Tessent Scan and ATPG User's Manual* for complete information.

Note

All generated files are placed in the *work_dft_debug* directory inside your working directory. This directory is created if it does not already exist.

When using the analyze_simulation_mismatches command for a pattern with a P53 violation, the tool issues an error and stops the DRC checking:

```
// Error: P53 violation may produce incorrect "analyze simulation
// mismatches" result.
// Suggest to fix the test procedure timeplate to avoid P53.
```

The problem of the P53 error is due to an undefined clock waveform in the used timeplate. Refer to the "Resolving P53 Errors for analyze_simulation_mismatches" for additional information on resolving this issue.

Arguments

- **-AUto**

  Required switch that automatically runs the entire simulation mismatch analysis on the currently loaded test patterns and design. This is the default behavior.

  The top-level design and Verilog library must be compiled in your work directory prior to starting the simulation mismatch analysis. The tool will search for a "work" directory within

the current working directory for these compiled files. Use the -Lib switch to specify a different directory.

The tool uses ModelSim as the Verilog simulator unless you specify a different simulator with the -Simulation_script switch.

- **-FAilure_file *failure_file***

  Required switch and string pair that specifies the pathname to an existing failure file to use for the simulation mismatch analysis. Using this switch bypasses Stages 1 and 2 of the analysis.

  -VCD_file ***vcd_filename***

  Optional switch and string that specifies the pathname of an existing simulation results VCD file for the mismatch analysis. This switch can only be used with the -FAilure_file switch. Using this switch bypasses the debug test bench simulation performed in Stage 4.

- **-MISmatches *mismatch_bit...***

  Required switch and repeatable string that specifies a list of mismatches to analyze instead of using a failure file.

  A *mismatch_bit* should be specified in one of the following formats:

  fail_pattern_index chain_name cell_index

  For example: "*1 chain5 20*" specifies the mismatch is on scan pattern 1, scan chain5, scan cell index 20.

  fail_pattern_index PO_name

  For example: "*2 xyz*" specifies the mismatch is on pattern 2 at PO signal *xyz*.

- ***Verilog_testbench_pathname***

  Optional string that specifies the pathname of an existing Verilog test bench for the invoking the old mismatch analysis. This option supports only ModelSim and performs an interactive communication to the Verilog simulator instead of dumping VCD data

- -Internal_patterns

  Optional switch that specifies the current internal pattern set for the mismatch analysis. This is the default.

- -External_patterns

  Optional switch that specifies the currently loaded external pattern set for the mismatch analysis.

Note

The serial test bench can take a long time to simulate for large designs. It is recommended that you analyze the parallel test bench first, then analyze the mismatches specific to the serial test bench.

- -SImulation_script ***simulator_invoke_script***

  Optional switch and string pair that specifies a simulation invocation script for the mismatch analysis. The script must invoke an external simulator and compile and simulate the test bench specified by the -PAtterns switch. By default, the analysis uses the simulator specified by the set_external_simulator command.

- -MAnual

  Optional switch to specify the "analyze simulation mismatch" functionality to stop at the step when the external Verilog simulator is needed. This option is useful when the Verilog simulation environment is complex and the simulation script can not be written directly. When specifying the step, the tool stops after saving Verilog test bench and gives an instruction for what to do next to complete the mismatch debugging flow. See Example 6.

Note

Note that the -MAnual and -SImulation_script switches are mutual exclusive.

- -SCan_test

  Optional switch that specifies that the tool only analyzes scan patterns. This is the default.

- -CHain_test

  Optional switch that specifies that the tool only analyzes chain patterns.

- -ALl_test

  Optional switch that specifies that the tool analyzes both scan and chain patterns.

- -Lib ***lib_name***

  Optional switch and string pair that specifies the pathname of the working simulation library. The working simulation library contains the compiled top-level design and any required parts libraries. By default, the tool uses the library named *work* in the same directory as the pattern test bench. For ModelSim applications, you must use this switch to specify a different library whether or not you enter the *vlib* command.

- -HOST ***server_name***

  Optional switch and string that specifies the name of a remote host on which to run the simulation portions of the mismatch analysis. The specified server must be accessible via rsh. For more information on rsh requirements, see "Multiprocessing Requirements" in the *Tessent Scan and ATPG User's Manual*.

- -TEstbench_for_vcd ***new_filename***

  Optional switch and string that specifies a file name for the debug test bench created in Stage 3 (default name *mentor_default.v_vcdtb.v*). The name of the simulation results VCD file is derived from the name specified by this switch. The default VCD dump file name created from the debug test bench is *mentor_default.v_debug.vcd*

- -REplace

  Optional switch that overwrites the *debug_testbench_filename* file if it already exists.

- -SHift_check { ON | OFF }

  Optional switch and literal that allows you to enable/disable checking for simulation mismatches that occur during the scan shift cycles. By default, the tool performs shift checking, but you might want to disable this feature for performance reasons after you are sure that shift operation is working properly.

  ON — Checks and reports if the scan shift cycle contains a mismatch between the Verilog simulation value and the ATPG expected value.

  OFF — Analyzes mismatches only on the capture cycles.

- -VErbose

  Optional switch that displays additional information about the simulation commands run in the background and the detailed mismatch data.

Example 1

The following example assumes the pathname of the ModelSim bin directory is defined by the PATH variable and that patterns are generated but not yet saved. This example demonstrates the automatic simulation mismatch analysis flow—see "Automatically Analyzing Simulation Mismatches" in the *Tessent Scan and ATPG User's Manual*.

The example first specifies the invocation command for the external simulator, then saves the generated pattern set. Next, it creates a Verilog library named *my_mismatch_work*, compiles the source for the top-level design and supporting simulation parts library into the library, and analyzes the simulation mismatches. DFTVisualizer is invoked and displays the simulation, test pattern, and design data with the mismatch sources highlighted in red.

report_mismatch_sources -display debug data wave
```

Example 2

This example demonstrates using the -failure_file switch when you have previously done Verilog simulation. This example assumes you have run an initial simulation to verify test patterns, generated a failure file, and created a script to set up and run an external simulator on a separate server from the ATPG session. The following example runs a simulation mismatch analysis on the specified failure file using internal test patterns on a separate server.

```
analyze simulation mismatch -failure_file pat.fs.v.fail -simulation_script runsim
```

```
// Running script "runsim pat.fs.v.fail_vcdtb.v" from local host to create VCD file pat.fs.v.fail_debug.vcd.
// Debug 24 internal patterns, CPU time = 0.02 sec
...
//  Step-5  Analyzing 24 internal scan patterns in parallel format.
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//    ID  instance (gate_id)  pattern-ix  time (ns)  seq_depth  ATPG_val  VCD_val  mismatch_reason
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//     1  /ix1286/Y (364)     scan-1           1900      0          1        0     incorrect library cell "and4"
//     2  /ix1278/Y (265)     scan-15         17300      0          1        0     incorrect library cell "and4"
```

For information on the output of this command, see the report_mismatch_sources command.

Example 3

This example shows the results of using the -failure_file and -vcd_file switches and shows a simulation script “runsim” for ModelSim:

```
#! /bin/csh -f
#Expect netlist has been compiled to work directory, next line commented
#vlog ~design/netlist.v -v ~/library/lib.v
vlog ${1}
vsim ${2} -c -do "run -all" -sdfmax /${2}/design_inst=~/design/good.sdf
```

Note that in the previous example, ${1} is the Verilog testbench name. The simulation script is used twice, first for running the testbench with the initial pattern set to get the failing bits, and then a second run for the reduced testbench to get the VCD file. Therefore, the vlog script needs to take a parameter instead of fixed testbench name. The ${2} is the Verilog testbench top instance name, which may change when the testbench name changes, so the name needs to be a parameter rather than a fixed name.

The following example uses the “runsim” script for automatic simulation mismatch analysis. Assume that the design and Verilog library have been compiled in advance in the work directory. After creating patterns, execute the following command:

analyze_simulation_mismatches -simulation_script runsim

```
// Running script "runsim work_dft_debug/mentor_default.v_vcdtb.v" from local host to create VCD file
work_dft_debug/mentor_default.v_debug.vcd.
...
//  ------------------------------------------------------------------------------------------
//  Step-5  Analyzing 24 internal scan patterns in parallel format.
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//    ID  instance (gate_id)  pattern-ix  time (ns)  seq_depth  ATPG_val  VCD_val  mismatch_reason
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//     1  /ix1286/Y (364)     scan-1           1900      0          1        0     incorrect library cell "and4"
//     2  /ix1278/Y (265)     scan-15         17300      0          1        0     incorrect library cell "and4"
```

Example 4

The following example shows a simulation script for NCVerilog:

```
#! /bin/csh -f
ncsdfc ../data/good.sdf
#Expect netlist to be compiled, next line commented out
#ncvlog ~/design/netlist.v -v ~/library/lib.v
ncvlog ${1}

#The following two commands create sdfcmdfile for ncelab to load SDF file
echo 'COMPILED_SDF_FILE = "~/design/top.sdf.X",' >! sdfcmdfile
echo "SCOPE = ${2}.design_inst;" >> sdfcmdfile
ncelab worklib.${2}:module -sdf_cmd_file sdfcmdfile
ncsim worklib.${2}:module
```

Example 5

The following example shows how to run a simulation analysis on a remote host.

analyze_simulation_mismatches -auto -host flea01 -simulation_script runsim

```
//  Simulation mismatch source is deleted.
//  Running script "runsim mentor_default.v_vcdtb.v" from flea01 to create VCD file mentor_default.v_debug.vcd.
//  Debug 25 internal patterns, CPU time = 0.02 sec
...
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//    ID  instance (gate_id)  pattern-ix  time (ns)  seq_depth  ATPG_val  VCD_val  mismatch_reason
//  ----  ------------------  ----------  ---------  ---------  --------  -------  ----------------------------
//     1  /ix1286/Y (364)     scan-1           1900      0          1        0     incorrect library cell "and4"
//     2  /ix1278/Y (265)     scan-15         17300      0          1        0     incorrect library cell "and4"
```

Example 6

The following example shows using the -MAnual switch:

analyze_simulation_mismatches

```
// ----------------------------------------------------------------------
// Step-1  Creating Verilog testbench work_dft_debug/mentor_default.v
// with failure file dump.
// ----------------------------------------------------------------------
// Manual flow is specified by user. Please simulate Verilog testbench
// work_dft_debug/mentor_default.v to create failure file
// work_dft_debug/mentor_default.v.fail.
// Then, "analyze simulation mismatch -fail
// work_dft_debug/mentor_default.v.fail" to generate reduced testbench
// with VCD dump.
```

Upon completion of this step, take the Verilog test bench *work_dft_debug/mentor_default.v* and perform the Verilog simulation to product the failure file *mentor_default.v.fail*.

Then, you issue the following command:

analyze_simulation_mismatches -fail work_dft_debug/mentor_default.v.fail -manual

```
// ----------------------------------------------------------------------
// Step-1  Loading failure file work_dft_debug/mentor_default.v.fail.
// ----------------------------------------------------------------------
// Step-2  Creating Verilog testbench
// work_dft_debug/mentor_default.v.fail_vcdtb.v with VCD dump.
```

```
// ----------------------------------------------------------------------
// Manual flow is specified by user. Please simulate Verilog testbench
// work_dft_debug/mentor_default.v.fail_vcdtb.v to create VCD file
// work_dft_debug/mentor_default.v.fail_debug.vcd.
// Then, "analyze simulation mismatch -fail
// work_dft_debug/mentor_default.v.fail -vcd
// work_dft_debug/mentor_default.v.fail_debug.vcd" to complete the
// analysis.
```

After this step, take the Verilog test bench *work_dft_debug/mentor_default.v.fail_vcdtb.v* and perform the Verilog simulation to product the VCD dump file *work_dft_debug/mentor_default.v.fail_debug.vcd*.

Finally, you use the following command to complete the task:

```
ATPG> analyze_simulation_mismatches -fail work_dft_debug/mentor_default.v.fail -vcd work_dft_debug/mentor_default.v.fail_debug.vcd
// ----------------------------------------------------------------------
// Step-1  Loading failure file work_dft_debug/mentor_default.v.fail.
// ----------------------------------------------------------------------
// Step-2  Loading VCD file
// work_dft_debug/mentor_default.v.fail_debug.vcd.
// ----------------------------------------------------------------------
// Step-3  Analyzing 2 internal scan patterns in parallel format.
// -- ------------------ ---------- --------- --------- -------- ------- ---------------------------------------
// ID instance (gate_id) pattern-ix time (ns) seq_depth ATPG_val VCD_val  mismatch_reason
// -- ------------------ ---------- --------- --------- -------- ------- ---------------------------------------
//  1 /u102/    (124)    scan-10    2100      0          0        X     incorrect loading during the main shifts
```

Related Commands

report_measure_cycles
report_mismatch_sources
write_patterns
set_external_simulator

analyze_test_points

Context: dft -test_points

Mode: analysis

Usage

analyze_test_points

Description

Specifies the test points analysis and generates a list of test points to be inserted by the tool.

Before performing the test point analysis, you can manually add test points using the add_control_points and the add_observe_points commands to add test points. You must do this prior to issuing the analyze_test_points command. Use the delete_test_points command to remove these manually added test points if you do not want the test points to be considered during analysis.

Note

When you have generated a list of test points with the “analyze_test_points” command, then these test points have to be deleted before you can modify the locations where test points are allowed. Any existing test points need to be deleted before issuing the command “add_notest_points” or “delete_notest_points” commands.

Note

Not all gates in the design will be considered by the tool for inserting test points. For various reasons test points will not be inserted on gates in the clock tree or in the scan path, gates in protected blocks, or gates where the user has explicitly requested that no test points should be inserted (via the “add_notest_points” command). If there are many locations where test points cannot be inserted the tool may not be able to find the best locations for test points. This may increase the number of test points that is needed to reach the fault coverage target. Therefore, if test points cannot be inserted at more than 20% of the gate-pins the tool will generate a warning. The warning specifies the number of these locations as well as the main reason(s) why test points cannot be inserted at these locations.

Arguments

None

Example 1

The following example specifies that a maximum number of 50 test points are to be generated for a design that will be tested with a set of 30000 random patterns. Then it performs the test points analysis based on these specifications. After the test points are reported to the screen they are inserted into the netlist:

```
set_system_mode analysis
```

set_test_point_analysis -total_number 50 -pattern_count_target 30000

analyze_test_points

report_test_points

insert_test_logic

Example 2

The following example generates 50 test points and performs the test point analysis. It then deletes all the existing test points, sets the attribute no_control_point to true and again performs test point analysis. After the test points are reported to the screen they are inserted into the netlist:

set_system_mode analysis

set_test_point_analysis -total_number 50 -pattern_count_target 30000

analyze_test_points

report_test_points

delete_test_points -all

set_attribute_value block1 -name no_control_point -value true

analyze_test_points

report_test_points

insert_test_logic

Related Commands

add_control_points

delete_test_points

analyze_wrapper_cells

Context: dft -scan

Mode: analysis

Usage

analyze_wrapper_cells

Description

Identifies shared and dedicated wrapper cells for the primary I/O ports.

This command launches the identification of the shared wrapper cells for the primary I/O ports that can be controlled with the set_wrapper_chains command. The user-specified clocks and scan-related I/O ports are automatically excluded from identification. The wrapper cells identified for the primary Inputs will be stitched into the separate Input wrapper chains, while the wrapper cells identified for the primary Outputs will be stitched into the separate Output wrapper chains. When the set_wrapper_chains command was not issued, the analyze_wrapper_cells command will perform the default wrapper cells identification similar to issuing the set_wrapper_chains command with no arguments.

When the analyze_wrapper_cells command is used in conjunction with the set_registered_io command or/and the “set_wrapper_chains –io_registration ON” command, the wrapper cells analysis will result in registration of the specified primary I/O ports or the primary I/O ports that have failed the shared wrapper cells identification with the dedicated wrapper cells to guarantee better test coverage of the circuit. This means that new scan cells will be added to all specified and failed primary I/O ports during scan insertion, subject to certain design considerations. The dedicated wrapper cells added to the primary Inputs will be stitched into the appropriate Input wrapper chains, while the dedicated wrapper cells added to the primary Outputs will be stitched into the appropriate Output wrapper chains.

When you use the set_wrapper_chains command, with or without the set_registered_io command, the identification includes the identification of existing sequential elements accessible via combinational logic from primary inputs or primary outputs as input/output registration cells (that is, shared wrapper cells). Thus, a shared wrapper cell serves a dual purpose of both functional mode, as well as the control and observe function during test. The advantage of shared wrapper cells is that less logic must be added and the external test mode (ExTest) can test the timing of the actual path.

The report_wrapper_cells command reports information about the identified wrapper cells for each primary I/O port subjected to wrapper cell identification.

Example

The following example illustrates the use of the analyze_wrapper_cells command:

```
set_wrapper_chains -input_sen se_in -output_sen se_out -input_gates_level 1 \
-output_gates_level 1 -io_registration on
set_system_mode dft

analyze_wrapper_cells
//  Number of targeted sequential instances = 6
//  Performing scan identification ...
//  Wrapper Cells Analysis ... (Inputs: 9, Outputs: 4)
//  Wrapper Cells Selection ...
//    5 cell(s) are selected for input wrapper chains.
//    0 cell(s) are selected for output wrapper chains.
report_wrapper_cells -verbose
-----------------------------------------------------------------------------------------------------------

analyze_xbounding

Context: dft -scan

Mode: analysis

Usage

analyze_xbounding

Description

Performs X-bounding analysis.

This command is used to identify memory elements (current scan cells or cells that will be converted to scan-in a subsequent run) that might capture an unknown value during Logic BIST. In addition, the command identifies where to place bounding muxes that will prevent these X-sources from reaching the memory elements and corrupting the signature during Logic BIST.

The X-bounding analysis uses the E5 DRC to identify and bound all X sources from reaching scan cells and corrupting the MISR. All primary inputs and internal X source pins (non scan cells, blackbox outputs pins etc.) will be x-bounded.

The X-bounding process depends on pin constraints on the primary input pins to indicate them as X sources. These X-constraints are implicitly enforced by this command, but can also come from existing input constraints. When a pin is explicitly constrained to either 0 or 1, it will not be treated as an X source.

The mux and scan cell library models used for X bounding can be specified using the cell_type attribute in the ATPG library or by the add_cell_model command. If any of the required library cell models are not specified, an error message will be issued.

The analyze_xbounding command also marks as notest points the previously observable gate pins that are on the input side of the x-bounding muxes. In addition, an X-source that does not feed into any scannable flops (for example, it simply connects to a primary output pin) will not be bounded. Any previously observable gate-pins that are driven by that X-source will also be marked as notest points.

Note

You must issue this command to perform X-bounding analysis. The tool does not automatically perform the analysis when you issue the insert_test_logic command.

Arguments

None

Example

This example transitions from setup to analysis mode, triggers the X-bounding analysis, and then reports the locations of the X-bounding muxes:

```
set_system_mode analysis
```

analyze_xbounding

report_xbounding -verbose

Related Commands

insert_test_logic

report_notest_points

report_xbounding

set_xbounding_options

annotate_diagnosis

Context: patterns -scan_diagnosis

Mode: analysis

Usage

annotate_diagnosis ***-directory_path*** [-force]

Description

Adds DFM and RCD data, if available, to existing diagnosis reports.

If there is already a DFM rule of the same name and type in the report, the tool replaces it. If there are already existing RCD feature statistics in the report, the tool replaces them.

Note

The set_diagnosis_options -include_dfm_rules and -include_rcd_constants switches do not affect the annotation process. Information is always preserved or added in the annotated diagnosis reports based on the content of the VDB or LDB that is open.

Arguments

- ***directory_path***

  A required string that specifies the directory path of a diagnosis report.

- -force

  An optional switch that specifies to bypass any issues with md5 compatibility that arise.

Example

The following example adds the DFM rules from the VDB to the flogs.ya diagnosis report.

```
open_layout design.ldb design.lddb
annotate_diagnosis flogs.ya
```

Related Commands

delete_dfm

import_dfm

append_to_collection

Context: unspecified, all contexts

Mode: all modes

Usage

append_to_collection ***var_name obj_spec*** [-unique]

Description

Adds one or more objects to a collection referenced by the specified var_name.

The append_to_collection command appends all elements in obj_spec to the collection referenced by the variable var_name. If the variable does not exist, the variable is created and made to point to a collection with elements from obj_spec as its value. An error is generated if the variable exists and does not reference a collection.

The result of the append_to_collection command is either a modification of the collection that was initially referenced by var_name or a new collection if the variable did not exist.

The append_to_collection command provides the same semantics as the add_to_collection command but with significant performance improvement. If you are building up a collection in a loop, using the append_to_collection command is more efficient as shown in Example 2.

Arguments

- ***var_name***

  A required value that specifies a Tcl variable name. The objects matching obj_spec are added to the collection referenced by this variable.

- ***obj_spec***

  A required value that specifies an object name, a Tcl list of object names, or a collection of objects to append to the collection referenced by var_name. The obj_spec can be an empty collection.

- -unique

  An optional switch that prevents duplicate objects from being appended to the collection. By default, duplicate objects are not removed.

Example 1

The following example appends a collection referenced by variable b to collection referenced by variable a.

```
set a [get_ports a*]
set b [get_ports b*]
append_to_collection a $b
```

Example 2

The following example creates a collection of all nets connected to pins of design instances matching u1/myPrefix*. Note that using the -unique option automatically removes duplicate

nets. This example is the same as the example shown for the add_to_collection command. Using the append_to_collection command for such an application is recommended and is much more efficient.

```
foreach_in_collection inst [get_instances u1/myPrefix* -of_type design] {
        set inputs [get_pins -of_instance $inst -direction input]
        set outputs [get_pins -of_instance $inst -direction output]
        append_to_collection sum [get_fanins $inputs -stop_on net] -unique
        append_to_collection sum [get_fanouts $outputs -stop_on net] -unique
}
```

apply_specification_defaults

Context: dft, patterns

Mode: all modes

Usage

apply_specification_defaults [***id***] [-design_name *design_name*]

Description

Automatically applies all defaults specified in the DefaultSpecification/DftSpecification wrappers to the DftSpecification wrappers that were created manually.

You can also use this command when creating a DftSpecification wrapper in the Configuration Data window. You do not need this command when using the create_dft_specification command because the create_dft_specification command automatically applies the specified defaults while creating the DftSpecification wrapper.

Arguments

- ***id***

  An optional string that specifies the DftSpecification wrapper that is to be processed. As described in the DftSpecification wrapper syntax, the wrapper is identified by the two strings “design_name” and “id”. If you only have one DftSpecification wrapper present in memory that matches DftSpecification(design_name,*), you can omit the id from the process_dft_specification command. However, if several DftSpecification wrappers matching DftSpecification(design_name,*) exist in memory, you must specify the appropriate id when executing the process_dft_specification command. Refer to the -design_name option to understand how the design_name value is obtained.

- -design_name *design_name*

  An optional switch and string pair that specifies the design_name value used to identify the DftSpecification wrapper. The -design_name value defaults to the current design if it has been set with the set_current_design command. If the current design has not been set, it is extracted from the DftSpecification wrapper existing in memory.

  When the id is specified, if exactly one wrapper matches “DftSpecification (*,<id>)” in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified. When the id is not specified, if exactly one wrapper matches “DftSpecification (*,*)” in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified.

Example

The following example calls the apply_specification_defaults command on a DftSpecification wrapper that was created manually to get the specified defaults found in the DefaultsSpecification/DftSpecification wrapper applied to the DftSpecification wrapper.

```
apply_specification_defaults
```

Related Commands

catch_output

Context: unspecified, all contexts

Mode: all modes

Usage

catch_output ***cmdline*** [-output *output_variable*] [-result *result_variable*] [-tee]

Description

Executes the specified tool command line, and may be used to prevent command errors from aborting the enclosing dofile or Tcl proc.

This command returns 0 if the embedded command succeeds and 1 if it fails.

You can use the -output switch to specify a variable to contain all of the output of the embedded command. You can use the -result switch to specify a variable to contain the Tcl result of the embedded command if the command returns one.

Arguments

- ***cmdline***

  A required string enclosed in braces "{ }" that specifies the command and associated arguments whose output you want to capture. The command is typically a report_* command. A return value of 1 indicates the command failed; a return value of 0 indicates the command succeeded.

- -output *output_variable*

  An optional switch and variable name that is set to the value of the entire command output.

- -result *result_variable*

  An optional switch and variable name that specifies to write the Tcl result returned by the embedded command to the result_variable variable.

- -tee

  An optional switch that specifies to write the command output to the transcript and to a logfile.

Example 1

The following example writes the result of the get_gate_pins command to the variable oVar; the result can be an error message if the command fails. If get_gate_pins fails, catch_output returns 1, and the "if" wrapper commands are executed.

The example also assigns the Tcl result returned by the get_gate_pins command to the rVar variable; the result is a collection if the command succeeds. If get_gate_pins succeeds, the catch_output command returns 0, and the "else" wrapper commands are executed.

The dofile continues even if the get_gate_pins command fails. Nothing is reported to the transcript.

```
if {[catch_output {get_gate_pins foo*} -output oVar -result rVar]} {
  # commands when get_gate_pins fails
} else {
  # commands when get_gate_pins succeeds
}
```

Example 2

The following example uses the catch_output command in a dofile to capture the output of a tool command in a variable.

```
set retVar [catch_output {report_gate /gate3} -output resultA -tee]
// /gate3  nor02
//      A0        I  /gate2/Y
//      A1        I  /ff2/Q
//      Y         O  /ff5/D  ff4/D  ff3/D /gate6b/E

If { $retVar == 0 }  {
   puts $resultA
}
// /gate3  nor02
//      A0        I  /gate2/Y
//      A1        I  /ff2/Q
//      Y         O  /ff5/D  ff4/D  ff3/D /gate6b/E
```

close_layout

Context: patterns -scan_diagnosis

Mode: analysis

Usage

close_layout

Description

Layout-Aware Diagnosis Flow

Closes the Layout Database. Any subsequent diagnosis you perform is non-layout aware.

SVDB Layout Marker Flow

Releases the Calibre Query Server and closes the layout. If you issue this command, then the tool no longer generates layout markers.

Arguments

None

Related Commands

create_layout

open_layout

close_pattern_set

Context: patterns -ijtag

Mode: analysis

Usage

close_pattern_set [-network_end_state keep | reset | initial]

Description

Finalizes and closes the currently open pattern_set.

If any iRead or iWrite commands remain that have not been processed by an iApply statement, a warning is printed and iApply processes them automatically.

By default, the end state of the ICL network is the one achieved normally by the last iApply statement. When the -network_end_state option is specified with the reset value, the ICL network will be written to such that all network elements are back to their reset state at the end of the pattern_set. When the -network_end_state initial value is used, all network elements are restored to the state they had at the beginning of the pattern_set.

Arguments

- -network_end_state

  keep — No special actions are taken when closing the pattern_set and the state of the ICL network remains in the state reached at the end of the last iApply command. This is the default.

  reset — Value is used when it is necessary to restore the reset state of the ICL network at the end of the *pattern_set*. The restoring of the state only applies to registers controlling select lines of ScanMultiplexers; the other registers are not reset. The restoring of the state is performed iWrite commands to the state control registers. Depending on the ICL network configuration, the restoring of the reset state is often achieved without extra scan operations but some network topology may require that extra scan loads be used.

  You use this option when you need to run multiple patterns immediately after this one without doing an iReset between them. Because the reset state is restored at the end of the *pattern_sets*, you can run them in arbitrary orders.

  initial — Value used when it is necessary to restore the state of the ICL network at the end of the *pattern_set* to what it was at the beginning of the *pattern_set*. The restoring of the state only applies to registers controlling select lines of ScanMultiplexers. The restoring of the state is performed with iWrite commands to the state control registers. Depending on the ICL network configuration, the restoring of the initial state is often achieved without extra scan operations but some network topology may require that extra scan loads be used.

  You use this option when you need to run the same pattern_set multiple times in a loop and the pattern_set does not perform an iReset at the beginning. In this case, it is important that the ICL state be identical at the beginning of the first run as it is at the

beginning all subsequent runs. The pattern_sets that are typically run in a loop are patterns that perform some kind of polling and the polling routine.

Return Value

None

Example

```
open_pattern_set pat1
iCall inst1.mytest
close_pattern_set -network_end_state initial
```

close_tsdb

Context: all contexts

Mode: all modes

Usage

close_tsdb ***directory_path_list*** | **-all** [-silent]

Description

Makes the content of previously opened TSDB directory invisible to the tool.

The specified TSDB output directory is automatically opened and cannot be closed with this command.

Arguments

- *directory_path_list*

  A value containing an absolute or relative path to a TSDB directory or a tcl list containing one or many absolute or relative paths to TSDB directories. You must specify either the directory_path_list or -all option, but you cannot specify both.

- -all

  An option to specify that all previously opened TSDB directory are to be closed. Note that the specified TSDB output directory is automatically opened and remains opened. You must specify either the directory_path_list or -all option, but you cannot specify both.

- -silent

  An optional switch that suppress the warning that is normally generated if the specified directory_path is not currently opened or if there are no opened TSDB directories when the -all option is used.

Examples

This example closes two TSDB directories with one command invocation.

```
> get_tsdb_list
/home/projects/chipa/tsdbs/corea.tsdb /home/projects/chipa/tsdbs/coreb.t
sdb /home/projects/chipa/tsdbs/corec.tsdb
> close_tsdb [list ${tsdb_home}/corea.tsdb \
                   ${tsdb_home}/coreb.tsdb ]
> get_tsdb_list
/home/projects/chipa/tsdbs/corec.tsdb
```

close_visualizer

Context: unspecified, all contexts

Mode: all modes

Usage

close_visualizer

DFTVisualizer Menu Path:
File > close_visualizer

Description

Saves display data and closes DFTVisualizer.

Display data is automatically saved and remains persistent for the current tool session.

Examples

The following example opens DFTVisualizer, displays the Debug window, and creates and displays a portion of the design, then closes the viewing session:

```
open_visualizer -display debug
add_display_instances i_16_7 -backward -end_point
close_visualizer
```

Related Commands

open_visualizer
write_window_contents
set_visualizer_preferences

compare_collections

Context: unspecified, all contexts

Mode: all modes

Usage

compare_collections ***collection1 collection2*** [-order_dependent]

Description

Compares the contents of two collections.

If the same objects are in both collections, the result is 0 (zero). If the objects in the collections are different, the result is a non-zero value. The order of the objects can optionally be considered by using the -order_dependent switch.

If two empty collections are compared, the compare_collections command considers them identical and returns a result of 0 (zero).

Arguments

- ***collection1***

  A required string that specifies the base collection for the comparison.

- ***collection2***

  A required string that specifies the collection to compare with collection1.

- -order_dependent

  An optional switch that causes the order of the objects to be considered when comparing the collections. The collections are considered to be different if the objects are ordered differently, and a non-zero value is returned.

Example 1

The following example shows a variety of comparisons.

```
set a [get_ports a*]
{a[3] a[2] a[1] a[0]}

set b [get_ports b*]
{b[3] b[2] b[1] b[0]}

set c [get_ports c*]
{}

#Same objects, same order
compare_collections $a $a
0

#Same objects, same order
compare_collections $a $a -order_dependent
0

#Different objects
compare_collections $a $b
1

#Different objects
compare_collections $a $b -order_dependent
1

#Two null collections
compare_collections $c $c
0

#Same objects, different order
compare_collections [add_to_collection $a $b] [add_to_collection $b $a]
0

#Same objects, different order
compare_collections [add_to_collection $a $b] [add_to_collection $b $a] -order_dependent
2
```

compress_layout

Context: patterns -scan_diagnosis

Mode: analysis

Usage

LDBs created after v2013.3: compress_layout [-REplace]

LDBs created with v2013.3 and before: compress_layout ***layout_database_name*** [-REPlace]

Description

Compresses a Layout Database.

You must open the Layout Database using the open_layout command before performing the compression operation.

See "Layout Database Compression and Decompression" in the *Tessent Diagnosis User's Manual* for complete information.

Arguments

- -REPlace

  An optional switch for overwriting an existing file.

- ***layout_database_name***

  A required string that specifies the location to and the name of the Layout Database to be created during the compression operation.

Related Commands

create_layout
open_layout
uncompress_layout

compress_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Usage

compress_patterns [*passes_integer*] [-Reset_au] [-MAx_useless_passes *integer*]
[-MIn_elim_per_pass *number*] [-MUltiple_detection [-Order]]
[-MIXed Essential | Order [-Delta *percentage*] [-Limit *integer*]]

Description

Compresses patterns in the current test pattern set.

Note

Mentor Graphics recommends you use create_patterns for the smallest pattern set. The compress_patterns command is for specialized processes.

The compress_patterns command performs static pattern compression on the current test pattern set by repeating fault simulation for the patterns in either reverse or random order and selecting only those patterns required for detection. The *passes_integer* argument specifies the number of pattern compression passes. The first pattern compression pass runs in reverse order and then alternates between random and reverse for additional passes. If you do not specify a *passes_integer* argument, the tool performs only one compression pass.

This is a multiprocessing command for fault simulation. For more information about multiprocessing, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual*.

If you specify the -Reset_au option, then when the tool performs pattern compression, it selects the AU faults for later fault simulation. If during pattern compression these AU faults simulate as possible-detected, the tool labels them as PU (possible-detected—ATPG_untestable), and they receive test coverage credit as possible-detected faults. If the number of pattern compression passes is greater than 1, the tool only performs the resetting of the AU faults for the first pass.

The compress_patterns command has a residual memory effect. The initial mode (reverse/random) is not fixed. Instead, it toggles back and forth, starting with the mode last used in the same run. The tool always starts with the reverse order at invocation.

If you include the -Multiple_detection switch, the static compression performed by this command will not simulate faults in the posdet (PD) fault class (PT and PU subclasses) and as a result, the tool may discard patterns that detect PD faults. Therefore, the test coverage reported after using this command switch may not be accurate if there are PD faults. To ensure you get the most accurate report of test coverage in this case, re-simulate the patterns using one of the following approaches:

- Enter the "set_system_mode analysis" command followed by the simulate_patterns command.
- Enter the order_patterns command with the -Simulate option.

Arguments

- *passes_integer*

  An optional integer that specifies the number of pattern compression passes. The default is 1 (performs only one compression pass).

- -Reset_au

  An optional switch that specifies fault simulation of AU faults.

- -MAx_useless_passes *integer*

  An optional switch and integer pair that specifies the maximum number of consecutive, useless (no eliminated patterns) passes the tool allows before terminating the pattern compression process. This command option has no effect on the pattern set if the number of passes (*passes_integer* argument) is smaller than the *integer* value of this switch. The default is the *passes_integer* value.

- -MIn_elim_per_pass *integer*

  An optional switch and integer pair that specifies the minimum number of eliminated patterns required in a single pass to continue the pattern compression process. If you specify this switch, you must enter a value greater than 0.

- -MUltiple_detection

  An optional switch that specifies for the tool to use a multiple detection based algorithm to carry out static pattern compaction. When you use this switch, the tool runs only one pass of compaction and discards patterns that detect only posdet (PD) faults.

- -Order

  An optional switch used with the -Multiple_detection switch to specify pattern ordering at the same time as static pattern compaction.

- -MIXed Essential | Order

  An optional switch and string pair that specifies to use a mixed compaction technique to compact the current internal pattern set. If you use the "Essential" option, the tool considers essential faults, those faults detected only once in the pattern set, as candidates for dynamic compaction. This option ensures that the patterns used to detect the essential faults are not dropped during pattern compression to keep the reached coverage.

  If you use the "Order" option, the tool selects fault candidates for dynamic compaction based on pattern set ordering.

Note

Using the "-Mixed Order" switch turns off pattern classification until you issue a "set_pattern_classification On" command.

Note

Mixed compaction can reduce the size of the current internal pattern set in most situations, but Mentor Graphics cannot guarantee that in every case the size of the pattern set after the tool performs mixed compaction will be less than the size of the pattern set before mixed compaction. Therefore, be sure to save the current internal pattern set before carrying out mixed compaction.

- -Limit *integer*

  An optional switch and integer pair that modifies the behavior of the -Mixed option. The -Limit switch specifies the maximum number of faults that the tool will attempt unsuccessfully to merge with the target fault pattern when dynamic compaction is involved. Without the -Limit switch, -Mixed causes the tool to use an adaptive algorithm to determine this number.

- -Delta *percentage*

  An optional switch and real number pair (between 0 and 100) that modifies the behavior of the -Mixed Order option. Normally, -Mixed Order selects fault candidates for dynamic compaction based on pattern set ordering. The -Delta switch causes the tool to consider as candidates for dynamic compaction, the specified percentage of the total number of faults instead of using pattern set ordering. The default percentage is 2.

Example

The following example compresses the generated test pattern set with two passes; the first pass is by reverse order and the second pass is by random order:

```
set_system_mode analysis
create_patterns
compress_patterns 2
```

Related Commands

add_processors
create_patterns
set_atpg_compression

copy_collection

Context: unspecified, all contexts

Mode: all modes

Usage

copy_collection ***collection***

Description

Duplicates the contents of an existing collection, resulting in a new collection. The base collection remains unchanged.

The only time you need to copy a collection is when you want to append to one copy while leaving the original copy unchanged. Copying a collection is equivalent to using add_to_collection with an empty collection as the second collection.

Arguments

- ***collection***

  A required string that specifies the collection to be copied.

Example

The following example shows the results of copying a collection and then appending to the copy. Notice how a2 is modified by append_to_collection, but a1 remains unaffected. The second reference to a2 called a3 sees the updated collection because it is simply a second reference to the same collection referenced by a2.

```
set a1 [get_ports a*]
{a[3] a[2] a[1] a[0]}

set a2 [copy_collection $a1]
{a[3] a[2] a[1] a[0]}

set a3 $a2

copy_module

Context: all contexts

Mode: insertion

Usage

copy_module ***obj_spec*** **-new_name** ***module_name*** [-silent]

Description

Creates an exact copy of a design module and assigns it a new name so that it can then be used as part of a create_instance and replace_instances.

The copy_module command returns a collection with one module object corresponding to the newly created module.

Arguments

- ***obj_spec***

  A required value that specifies a module name or a collection containing a single module object as returned by the get_modules command.

- **-new_name** ***module_name***

  A required switch and value pair that specify the name of the new module once it has been copied. If module_name already exists, the module is copied and "_integer " is appended to the end of the module_name where integer increments as each new module of the same name is added.

- -silent

  An optional switch that suppresses the error that is normally generated if obj_spec does not point to a single module that exists. A null collection is returned when an error was suppressed. This option also suppresses the error that is generated if the specified ***module_name*** already exists.

Example 1

The following example creates a copy of module ModA to ModB. ModB is identical to ModA and can be instantiated into the design.

copy_module ModA -new_name ModB

```
{ModB}
```

Example 2

The following example introspects the module name of an instance to create a copy.

copy_module [get_att_value u1/u2 -name module_name] -new_name ModB

```
{ModB}
```

copy_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: A flat model must currently exist

Usage

copy_simulation_context [-from *source_context_name*] [-to *target_context_name*]

Description

Copies the simulation values and forces from one simulation context to another.

The copy_simulation_context command copies the simulation values and forces from any predefined or user-defined simulation context to any user-defined simulation context.

Note that you must specify either the -to or the -from switch, or specify both switches.

Arguments

- -from *source_context_name*

  An optional switch and string pair that specifies the simulation context from which to copy the simulation values and forces. The source_context_name can be predefined (listed in Table 7-40 on page 1648) or user-defined. If you don't use this switch and you do supply the -to switch, the command uses the current simulation context as the source_context.

- -to *target_context_name*

  An optional switch and string pair that specifies the simulation context to which to copy the simulation values and forces. The target_context_name can be any user-defined context name that already exists and cannot be a predefined context name (listed in Table 7-40 on page 1648). If you don't use this switch and you do use the -from switch, the command uses the current simulation context as the target_context.

Example

The following examples show two ways to copy the simulation values of the predefined simulation context, stable_load_unload, to the user-defined simulation context, myContext:

```
SETUP> set_current_simulation_context myContext
SETUP> copy_simulation_context -from stable_load_unload
```

You can accomplish the same as the above with a single command:

```
SETUP> copy_simulation_context -from stable_load_unload -to myContext
```

create_capture_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Usage

create_capture_procedures [-Name *capture_procedure_name*]
{**-PAtterns** [Internal | External] [*pattern_index*...] |
{{**-Clock_sequence** ***clock_sequence*** | **-SAME_clocks_pulse**
{**SIngle_clock_per_procedure** | **GRoup_noninteracting_clocks_per_procedure**}
[*pulse_times*]}
[-FORce_pi [*cycle_number*...]] [-MAsk_po] [-SLow_cycles {***cycle_number***...}]
[-Load_cycles {***cycle_number***...}] [[-COndition *pinpathname value* [*cycle_number*...]]...]
[[-TImeplate [Fast | Slow] *timeplate_name*]...]
[{-EXT_Clock_sequence *clock_sequence* | -EXT_Same_clock_pulse *external_clock_name pulse_times*} [-EXT_Timeplate *timeplate_name*]]} [{>|>>} *file_pathname*]

Description

Creates named capture procedures based on clock sequences either derived from patterns or specified at the command line.

The create_capture_procedures command is used before or after pattern generation. This command creates the procedures in the internal memory only. You can save the procedure to a test procedure file using the write_procfile command.

For information on using named capture procedures, see "At-Speed Test Using Named Capture Procedures" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- -Name *capture_procedure_name*

  An optional switch and string pair that specifies the name of the capture procedure to create. If there is already a procedure with this name, a suffix is added to the name specified. If multiple named capture procedures are created, the specified *capture_procedure_name* is used as the prefix of each name and a suffix is added. If -Name is not specified, the default name is *user_capture_proc1*, *user_capture_proc2*, and so on.

- **-PAtterns** [Internal | External] [*pattern_index*...]

  A switch that specifies which patterns to extract clock sequences from for the named capture procedures. The following options are available:

  [Internal | External] — An optional literal that extracts clock sequences from internal or external patterns. The default is internal if not specified.

  [*pattern_index*...] — An optional, repeatable string that extracts clock sequences from the patterns with the specified index. The pattern index starts at 1. By default, the tool extracts clock sequences from all the patterns of the internal or external pattern set if a pattern index is not specified.

- **-Clock_sequence *clock_sequence***

  A switch and string pair that specifies the clock sequence for the named capture procedure. *clock_sequence* is a sequence of cycles. A cycle is denoted by one or more clocks enclosed by a pair of parentheses. Adjacent clocks within a cycle must be separated by either white space or a comma. The clock is designated by the gate identification number or pin pathname. For example, (c1,c2) (c1) (c2,c3) represents a clock sequence with three cycles. In the first cycle, clock c1 and c2 are pulsed; in the second cycle, clock c1 is pulsed; in the third cycle, clock c2 and c3 are pulsed.

- **-SAME_clocks_pulse** {**SIngle_clock_per_procedure** | **GRoup_noninteracting_clocks_per_procedure**} [*pulse_times*]

  A switch, literal, and optional value that automatically generate intra clock domain named capture procedures.

  SIngle_clock_per_procedure — A literal that pulses a single clock in every pulse cycle. A named capture procedure is automatically created for every clock in the design that is not constrained to its offstate value. Also, all clocks defined as its equivalence are pulsed when a single clock is pulsed in every cycle.

  GRoup_noninteracting_clocks_per_procedure — A literal pulses a clock group, which consists of a group of non-interacting clocks in every pulse cycle. Each clock group consists of a maximal set of non-interacting clocks. Once clocks are classified into groups, a named capture procedure is created for every clock group. (To understand the difference between non-interacting and interacting clocks, see the description of interacting clocks in the “domain_clock” and “-any_interaction” options in the set_clock_restriction command.)

  pulse_times — An optional value that specifies the number of cycles that pulse clock(s). By default, *pulse_times* is 2 if not specified.

- -FORce_pi [*cycle_number*...]

  An optional switch and repeatable integer that force PI values in the specified cycle(s). If *cycle_number* is not specified, all the cycles contain the force_pi statement. By default, only the first cycle contains the force_pi statement. The cycle number starts at 1.

- -MAsk_po

  An optional switch that specifies the last cycle contains the no measure_po statement. By default, the last cycle contains measure_po to indicate the time when the PO measurement happens.

- -Slow_cycles {*cycle_number*...}

  An optional switch and repeatable integer that specify the slow cycles of the procedure.

- -Load_cycles {*cycle_number*...}

  An optional switch and repeatable integer that specify where the scan load happens before the capture cycles of the procedure. By default, only the single scan load happens before the first cycle.

- -COndition *pinpathname value* [*cycle_number*]

  An optional switch, pin pathname, integer, and cycle integer that specify a condition of the scan cells in the named capture procedure. If *cycle_number* is not specified, the condition is a global condition; otherwise, the condition is a local condition associated with the specified cycle only.

- -TImeplate [Fast | Slow] *timeplate_name*

  An optional switch, literal, and string that specify the timeplate for the fast or slow cycles of the named capture procedure. By default, the specified timeplate applies to the fast cycles of the named capture procedure.

  If this optional switch is not specified, the default timeplate is used for the named capture procedures. You can define the default timeplate by specifying the Set Default_timeplate statement in the procedure file.

- -EXT_Clock_sequence *clock_sequence* | -EXT_Same_clock_pulse *external_clock pulse_times* [-EXT_Timeplate *timeplate_name*]

  An optional switch, string, and value that automatically create the external mode of the named capture procedures. This switch should not be used together with the **-Patterns** switch.

  -EXT_Clock_sequence *clock_sequence* — An optional switch and string pair that specifies the clock sequence for the external mode of the named capture procedure. *clock_sequence* is a sequence of cycles. A cycle is denoted by one or multiple clocks enclosed by a pair of parentheses. Adjacent clocks within a cycle must be separated by either white space or a comma. The designated clock(s) must be external clock(s).

  -EXT_Same_clock_pulse *external_clock pulse_times* — An optional switch, string, and value that specify to pulse an external clock in every cycle in the external mode. You can specify the external clock by its gate identification or pin pathname. *pulse_times* specifies the number of cycles that pulse the external clock.

  -EXT_Timeplate *timeplate_name* — An optional switch and string that specifies the timeplate to use for the external mode of the named capture procedure. The default timeplate is used if this optional switch is not specified.

- > *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list to create or replace the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list to append the contents of *file_pathname*.

Example 1

The following example creates named capture procedures based on the clock sequences extracted from internal patterns.

```
set_system_mode analysis
create_patterns
create_capture_procedures -name my -patterns internal
```

Example 2

The following example creates named capture procedures based on the clock sequences extracted from the 1st, 12th, and 20th patterns in the external pattern set.

```
read_patterns pattern_file
create_capture_procedures -name my -patterns external 1 12 20
```

Example 3

The following example creates a named capture procedure of two cycles for every non-constrained clock in the design.

```
create_capture_procedures -same_clocks single 2
```

Example 4

The following example creates a named capture procedure with a user-defined clock sequence. The defined clock sequence has four clock cycles. In cycle 1, clock1 is pulsed. In cycle 2, clock1 and clock2 are pulsed simultaneously. In cycle 3, clock1 and clock3 are pulsed simultaneously. In cycle 4, clock1 is pulsed and PO is measured. In this example, all cycles are at speed cycles.

```
create_capture_procedures -clock_sequence (clock1) (clock1, clock2) (clock1, clock3) \
(clock1)
```

Example 5

The following example creates a named capture procedure using the same clock sequence defined in the previous example. In the first cycle, the scan cell needs to satisfy the condition of having the loading value of 1.

```
create_capture_procedures -clock_sequence (clock1) (clock1, clock2) (clock1, clock3) \
(clock1) -condition /inst_core/inst_iacc/inst_reg 1 1
```

create_connections

Context: all contexts

Mode: insertion

Usage

Usage 1: 1-to-1 pairing connections

create_connections ***object_spec1 object_spec2***
[-net_name *net_name*] [-silent]

Usage 2: 1-to-Many broadcast connections

create_connections ***object_spec1 object_spec2***
[-net_name *net_name*] [-silent]

Usage 3: Many-to-1 constant connections

create_connections ***object_spec1*** **-constant {1 | 0}**
[-net_name *net_name*] [-silent]

Description

Connects pin, net, or port objects.

You can connect any of the object types pins, nets, or ports as described here:

Usage 1: When ***object_spec1*** and ***object_spec2*** contain the same number of elements, the tool pairs the elements from the two lists in the order of the two lists and creates a connection between each pair. Only one driver element per pair is allowed.

Usage 2: When ***object_spec1*** has one element, and ***object_spec2*** has one or more elements, object_spec2 cannot include any driver elements, such as an input port or an output pin.

Usage 3: When you specify -constant, you cannot specify ***object_spec2*** and ***object_spec1*** cannot contain any driver element, such as an input port or an output pin.

When the -net_name option is not specified, the net and pin name used to create the connection is automatically inferred from the name of the elements within object_spec1 using the following algorithm:

- If the element in ***object_spec1*** is a pin, the tool uses the leaf_pin_name unless it has fewer than three characters; if it has fewer than three characters, the tool uses the leaf_instance_name of the pin concatenated with the leaf_name of the pin and separated by an underscore.
- If the element in ***object_spec1*** is a net or a port, the tool uses the leaf name irrespective of the number of character it has.

You can override the default net name by using the -net_name switch and specifying the net_name option to be used to create the intermediate nets and pins. Regardless of whether the default or a user-specified net name is specified, the tool checks for net conflicts and uniquifies

the newly created net to avoid accidental shorts. The uniquify operation is performed using the net_uniquification_string suffix specified with the set_insertion_options command.

The two endpoints of each connection may be in different parts of the design hierarchy. The tool creates all of the intermediate pins needed to create the connection through the hierarchy. The tool automatically reuses existing pins that already make up part of the requested connection.

If you connect more than one pin within a given instance to a common source outside the instance, the tool creates only a single pin on the instance interface and reuses that same pin for all of the desired connections specified within the instance.

Arguments

- ***object_spec1 object_spec2***

  A required value that specify a set of endpoints of the connections to be created. The value of the object_spec argument can be a single pin, port or net name; a Tcl list of pin, port, or net names; or a collection of pin, port, or net objects.

  The size of ***object_spec1*** must either be one or equal to the size of the ***object_spec2*** when ***object_spec2*** is specified. The ***object_spec1*** argument cannot include any driver elements when you specify the -constant option. At most, one driver can exist in each connection pair when you specify both ***object_spec1*** and ***object_spec2***.

  If an object does not exist within one of the **object_spec** and you specify the -silent option, the tool ignores the object and skips the connection request. If the object does not exist and you do *not* specify the -silent option, the tool generates an error.

- -constant 1 | 0

  A switch and literal pair that specifies a constant value to connect to all elements within ***object_spec1***. The -constant switch is mutually exclusive with the ***object_spec2*** argument.

  When this option is specified, the ***object_spec1*** argument cannot contain any driver elements such as input ports or output pins. In Verilog, a 1'b0 or 1'b1 connection is used as the connection to the pins, and a buf primitive or an assign statement with its input connected to 1'b0 or 1’b1 is used as the connection to output ports or to nets.

- -net_name *net_name*

  An optional argument that specifies the name of the pin created on ***object_spec1*** or ***object_spec2*** to route the connection. If –net_name is not specified, the tool uses the leaf name of object_spec1 to name the pin. If object_spec1 is a pin and its leaf name has fewer than three characters, the tool uses the leaf instance name of the base name of the pin concatenated with the leaf pin name and separated by an underscore.

- -silent

  An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages. Connections with at least one non-existent object are skipped.

Example 1

The following example illustrates Usage 1 and creates a connection between three scalar ports and a 3-bit bus pin. The pin name created on u2 to route the connection is u2_a[2:0]. This pin name is constructed by concatenating the leaf_instance_name of u1/u2/a with the leaf_name of pin a with an underscore, because it has fewer than three characters.

```
create_connections u1/u2/a[2:0] {a b c}
```

Example 2

The following example illustrates Usage 2 and creates three connections between port IN1 and pins blockA/modB/u1/a, blockA/modB/u2/a, and blockA/modC/u1/a. The command creates a single net called myname on u1, u1/u1 to make all three connections.

```
create_connections IN1 {blockA/modB/u1/a blockA/modB/u2/a blockA/modC/u1/a} \
–net_name myname
```

Example 3

The following example illustrates usage 3 and connects all pins matching the name ABC*/TE to a constant 0 value.

```
create_connections [get_pins ABC*/TE -hier] -constant 0
```

create_dft_specification

Context: dft

Mode: analysis

Usage

create_dft_specification [-existing_ijtag_host_scan_in *host_scan_in_design_pin_spec*] [-replace]

Description

Creates the "DftSpecification(design_name,id)" configuration wrapper and returns the newly created wrapper object so that it can be stored in a variable and used to customize the created specification.

This command finds Ijtag instances in the design that need to be connected to the IjtagNetwork and automatically creates the IjtagNetwork wrapper to connect them. The command supports multiple DFT insertion passes into any given module. The tool excludes elements seen to already be connected to the network from the current specification. An Ijtag instance is automatically seen by the command if its ICL file was loaded and the ICL module was matched to the design module during elaboration. See the "set_design_sources -format ICL" and the set_module_matching_options command descriptions for more details about this process. Use report_ijtag_instances or get_ijtag_instances to see which instances have a matched ICL module.

create_dft_specification.post_create callback procedure:

The DefaultsSpecification/DftSpecification wrapper has many options to help you customize how the created DftSpecification is created. You may however still have custom changes you want to implement on the created specification. You can easily automate these changes using the configuration introspection commands and setting commands to edit the "DftSpecification(design_name,id)" configuration wrapper as shown in Example 2 below.

The create_dft_specification.post_create procedure must have two arguments as shown here. The first argument holds the config wrapper name that is currently being created. The second argument holds a list of option value pairs corresponding to the options that were used when the create_dft_specification command was called.

```
proc create_dft_specification.post_create { root_wrapper args } {

  # "$root_wrapper" is the config_element object being created.
  # "get_config_value $root_wrapper -id 0" returns the design_name
  # "get_config_value $root_wrapper -id 1" returns the id

  # "$args" is a list of option value pairs that reflects the options used
  # when the process_dft_specification command was called.

  array set extra_args $args

  # $extra_args(-existing_ijtag_host_scan_in) returns the value of
  # that option
```

```
}
```

How the IjtagNetwork specification is created

The set_design_level command is used to define the target usage level of the current design. When the level is set to “chip”, the IJTAG interface created by the create_dft_specification command is a client Tap interface. When the level is set to “physical_block” or “sub_block”, it is a client IJTAG interface.

For the first dft insertion pass containing any IJTAG component, a root level IJTAG ring is created with one or two Sibs in series. The two sibs are called Sib(sti) and Sib(sri) and are inserted on demand when needed by the current insertion pass if it was not already inserted by a prior insertion pass. The Sib(sti) provides access to the IJTAG network for all instruments in the current design that are to be scan tested along with the rest of the functional logic by the logictest modes such as EDT or LogicBist. The acronym “sti” refers to “Scan Tested Instrument”. As shown in Figure 5-9 on page 145, that Sib provides isolation between its host port and its clients. The Sib(sri) is used to provide access to the IJTAG network for child physical blocks, and for logictest instruments and Tdrs used to configure the logictest modes. The acronym “sri” refers to “Scan Resource Instrument”. These IJTAG nodes must remain active and undisturbed during the logictest modes, and are excluded from the logictest scan chains. An ICL module is identified as a Scan Resource Instrument when it has the ICL module attribute called “keep_active_during_scan_test” set to “true”.

At the chip level, a TAP controller is inserted on the first insertion pass unless the -existing_ijtag_host_scan_in option of the create_dft_specification command has been used to reference a design pin. The design pin must be on an instance having an associated ICL module and the pin must be a ScanInPort referenced by a Host ScanInterface wrapper. Those different scenarios are illustrated in the Example 1 section below.

Any instance of a module having a corresponding ICL module will, by default, be inserted into the IjtagNetwork wrapper of the DftSpecification unless it is seen as being already connected to the network. The set_ijtag_instance_options command or the tessent_use_in_dft_ specification icl_module attribute can be used to change the default behavior.

Different ICL elements (ScanInterfaces, DataInPorts, and DataOutPorts) seen in the circuit are handled by this command as described here:

- Client ScanInterface — A Client ScanInterface is referenced by a DesignInstance wrapper when it is to be inserted into the network as part of the current DftSpecification. It is not referenced by the current IjtagNetwork when the ScanInPort associated to the Client ScanInterface has its attribute “has_functional_source” set to true. You can use the set_ijtag_instance_options command to force its inclusion or exclusion independent of the value of the has_functional_source attribute.

  If the ScanInterface is on an instance that is defined as a physical block (as defined by the tessent_is_physical_ module attribute of its ICL module), it will be inserted below the Sib(sri).

  If the ScanInterface is on an instance that is not defined as a physical block (as defined by the tessent_is_physical_ module attribute of its ICL module), it will be inserted

behind the Sib(sti) or Sib(sri) based on the value of the "keep_active_during_scan_test" attribute on its ICL module.

- DataInPorts — A DataInPort is referenced by a connection property inside the Tdr/DataOutPorts wrapper when it is to be controlled by the network. The DataInPort is not referenced by the current IjtagNetwork when there is already a DataOutPort in its fanin. If the DataInPort has a functional source, a multiplexer will be inserted to allow controlling it by the IjtagNetwork in test mode without disturbing its functional source its mission mode. You can use the set_ijtag_instance_options command to force its inclusion or exclusion independent of whether it has a DataOutPort in its fanin.

  If the instance on which the DataInPort exists has the keep_active_during_scan_test attribute defined and set to true, the Tdr sourcing the DataInPort will be inserted behind the Sib(sri) so that it is kept active and not part of the scan chain during the scan test modes. If the keep_active_during_scan_test attribute is off, the Tdr sourcing the DataInPort will be inserted behind the Sib(sti) so that it can be scan tested along with the rest of the functional logic.

- DataOutPorts — A DataOutPort is referenced by a connection property inside the Tdr/DataInPorts wrapper when it is to be observed by the network. It is not referenced by the current IjtagNetwork when there is already a DataInPort in its fanout. You can use the set_ijtag_instance_options command to force its inclusion or exclusion independent of whether it has a DataInPort in its fanout.

  If the instance on which the DataOutPort exists has the keep_active_during_scan_test attribute defined and set to true, the Tdr observing the DataOutPort will be inserted behind the Sib(sri) so that it is kept active and not part of the scan chain during the scan test modes. If the keep_active_during_scan_test attribute is off, the Tdr observing the DataOutPort will be inserted below the Sib(sti) so that it can be scan tested along with the rest of the functional logic.

Licensing

This command normally requires an IJTAG product license to run. There is one exception to this requirement. If the design contains one or more instances of an EDT/LBIST controller, the TestKompress/LogicBist licenses are also allowed to run this command. In this case, the tool checks the availability of the license in the following order: IJTAG, TestKompress, LogicBist. If none are currently available, the tool queues up for the first license that you own.

You can refer to the set_license_queue_timeout and get_license_queue_timeout commands for more information about the license queuing feature.

Arguments

- -existing_ijtag_host_scan_in *host_scan_in_design_pin_spec*

  A optional option value pair that defines an existing host scan interface to which the entire IjtagNetwork should attach to inside the created DftSpecification. The design pin must be on an instance having an associated ICL module and the pin must be a ScanInPort referenced by a Host ScanInterface wrapper. You should only specify this option during the

first insertion pass. When unspecified, the interface to the ijtag network is determine using several criteria. When it is not the first insertion pass into the current design and either the Sib(sti) or the Sib(sri) is seen, it is automatically used as the connection point for the current insertion pass as illustrated in Step 2 of the example below. If it is the first insertion pass, a tap is inserted to host the root level Sib ring when design level is chip. The root level Sib ring is connected to ports when at the physical_block or sub_block level. The design level is specified as chip, physical_block or sub_block using the set_design_level command.

- -replace

  A optional switch that suppresses the error that normally occurs if the DftSpecification(design_name,id) configuration wrapper already exists in memory. Instead, the existing one is deleted and replaced by the newly created one.

Example 1

The following example illustrates the created DftSpecification that is generated by the create_dft_specification command when running on different modules of a chip. The examples below are useful to understand how instruments are connected to the IjtagNetwork in a multi-insertion pass scenario.

Step 1

The first run is performed on a core called CoreA to create and hook up instruments to the network. These instruments are scan testable (keep_active_during_scan_test is off). It is the first dft insertion pass involving the IjtagNetwork in that module so the tool creates the Sib(sti) in this run.

```
set_context dft -rtl
#commands to load design apprears here

set_current_design CoreA
set_design_level physical_block

set_system_mode analysis

set spec [create_dft_specification]
```

The generated DftSpecification is shown below. The Sib(sti) is identified with the "tessent_dft_function" attribute set to "scan_tested_instrument_host". All local scan interfaces are daisy chained below the Sib(sti_local).

```
DftSpecification(CoreA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Sib(sti) {
        Attributes {
          tessent_dft_function : scan_tested_instrument_host;
        }
        Sib(sti_local) {
          DesignInstance(tdr_1) {
            scan_interface : client;
          }
          DesignInstance(tdr_1) {
            scan_interface : client;
```

```
            }
          }
        }
      }
    }
  }
```

Step 2

The second run is again performed on the core called CoreA at a later time to insert a Tdr used to control DataInBits on a scan control module that was user-inserted after the original insertion phase. The scan control module has an associated ICL file which documents its DataInPorts and with the ICL module attribute keep_active_during_scan_test set to on. Notice that because this is a second insertion pass into the same design module, the design_id is specified as rtl2 in the set_context command to differentiate the insertion pass from the previous one. An error would have been generated had it not been specified because a conflict would have been noticed from the existence of instances of module names whose names start with “CoreA_rtl_tessent_”.

```
set_context dft -rtl -design_id rtl2

#commands to load design apprears here

set_current_design CoreA
set_design_level physical_block

set_system_mode analysis

set spec [create_dft_specification]
```

The generated DftSpecification is shown below. The Interface wrapper of the HostScanInterface wrapper is used to specify that the new Sib(sri) is to be inserted in series with the client interface of the Sib instance “CoreA_rtl_tessent_sib_sti_inst” which is the Sib(sti) created in the first insertion pass.

```
DftSpecification(CoreA,rtl2) {
  IjtagNetwork {
    HostScanInterface(sri) {
      Interface {
        design_instance : CoreA_rtl_tessent_sib_sti_inst;
        scan_interface : client;
      }
      Sib(sri) {
        Attributes {
          tessent_dft_function : scan_resource_instrument_host;
        }
        Sib(sri_local) {
          Tdr(sri_tdr1) {
            DataOutPorts {
              connection(0) : scan_control_inst/tm;
              connection(1) : scan_control_inst/ac_mode;
              connection(3:2) : scan_control_inst/config[1:0];
            }
          }
        }
      }
```

```
        }
      }
    }
```

Step 3

The third run is performed on the chip called ChipA. It is used to provide access to the IJTAG scan interface of the 2 instances of CoreA and to again insert a Tdr to control the data_in ports of the scan control module situated at the top level. A Tap wrapper is created as the -existing_ijtag_host_scan_in option was not specified and the Tap from a previous insertion pass was not seen as this is the first insertion pass at the chip level.

```
set_context dft -rtl

#commands to load design apprears here

set_current_design ChipA
set_design_level chip

set_system_mode analysis

set spec [create_dft_specification]
```

The generated DftSpecification is shown below. Notice how a Tap wrapper is being specified. It includes a HostBscan wrapper such that the TAP is ready for boundary scan-in a future insertion pass. One sib is inserted into the root level Sib ring to interface to the two instances of CoreA, and to provide access to the Tdr that is inserted to control the DataIn ports of the scan control module. Each child physical block is also wrapped by a local Sib to make sure other parts of the network are always accessible even if the physical block is defective, powered down, or in simulation, black-boxed.

```
DftSpecification(ChipA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Tap(main) {
        HostBscan {
        }
        HostIjtag(1) {
          Sib(sri) {
            Attributes {
              tessent_dft_function : scan_resource_instrument_host;
            }
            Sib(pb1) {
              DesignInstance(CoreA_I1) {
                scan_interface : ijtag;
              }
            }
            Sib(pb2) {
              DesignInstance(CoreA_I2) {
                scan_interface : ijtag;
              }
            }
            Sib(sri_local) {
              Tdr(sri_tdr1) {
                DataOutPorts {
                  connection(0) : scan_control_inst/tm;
```

```
                    connection(1) : scan_control_inst/ac_mode;
                    connection(2) : scan_control_inst/config2;
                  }
                }
              }
            }
          }
        }
      }
    }
  }
```

Step 3 could have been modified to connect to an existing TAP controller by simply using the -existing_ijtag_host_scan_in option as follows:

create_dft_specification -existing_ijtag_host_scan_in mytap/from_bist0

The created DftSpecification would then be as follows

```
DftSpecification(ChipA,rtl) {
  IjtagNetwork {
    HostScanInterface(ijtag) {
      Interface {
        DesignInstance (mytap) {
          scan_interface : BistPort0;
        }
        Sib(sri) {
          Attributes {
            tessent_dft_function : scan_resource_instrument_host;
          }
          Sib(pb1) {
            DesignInstance(CoreA_I1) {
              scan_interface : ijtag;
            }
          }
          Sib(pb2) {
            DesignInstance(CoreA_I2) {
              scan_interface : ijtag;
            }
          }
          Sib(sri_local) {
            Tdr(sri_tdr1) {
              DataOutPorts {
                connection(0) : scan_control_inst/tm;
                connection(1) : scan_control_inst/ac_mode;
                connection(2) : scan_control_inst/config2;
              }
            }
          }
        }
      }
    }
  }
}
```

Example 2

Below is an example of a Tcl proc that can be defined that will remove the HostBscan wrapper created inside the Tap wrapper. A wrapper called HostBscan is searched below the DftSpecification and deleted if it exists. The callback is automatically called inside the create_dft_specification command after the DftSpecification wrapper is created in memory.

```
proc create_dft_specification.post_create {config args} {
  set HostBscan_wrp [get_config_el HostBscan -hier -in $config -silent]
  if {[sizeof_collection $HostBscan_wrp] > 0} {
    delete_config_elements $HostBscan_wrp
    puts "post_create: Removing the HostBscan wrappers: [get_name_list \
          $HostBscan_wrp]"
  }
}
```

create_diagnosis_patterns

Context: patterns -scan_diagnosis

Mode: analysis

Usage

Logic Failure Diagnosis

create_diagnosis_patterns [-DIAGnosis_report {*diagnosis_report1 diagnosis_report2* ...}] [-MAX_pattern_count [*number*]] [-TRAnsition]

Scan Chain Failure Diagnosis

create_diagnosis_patterns [-DIAGnosis_report {*diagnosis_report*}] [-CHAIN *chain_name*] [-CELL_range *lowerbound upperbound*] [-FAULT_type {stuck_at_0 | stuck_at_1 | slow_to_rise | slow_to_fall | slow | fast_to_rise | fast_to_fall | fast}]

Description

Creates targeted patterns for logic failure or scan chain failure iterative diagnosis.

For usage cases using this command, refer to "Iterative Logic Diagnosis Examples" in the *Tessent Diagnosis User's Manual*. You can use iterative diagnosis with the layout-aware diagnosis flow as long as you use the layout in the same iterative diagnosis session—see "Layout-Aware Diagnosis" in the *Tessent Diagnosis User's Manual*.

Note

After issuing this command, you should write out the test patterns to an external file using the write_patterns command.

Logic Failure Diagnosis: The tool loads the diagnosis result from a prior run or a diagnosis report file, create a fault list, and generates the patterns targeting suspect signals in the diagnosis report.

Scan Chain Failure Diagnosis: The tool loads either of the following inputs you specify:

- A diagnosis report file containing the diagnosis results of scan chain failure.
- The chain names, scan cell range, and the fault type.

For scan chain failure diagnosis, you can also provide a chain name (using the –chain switch) and a diagnosis report containing multiple faulty scan chains. In this case, the diagnostic test generation only creates patterns for the scan chain specified by the –Chain switch.

Logic Failure Diagnosis Arguments

- -DIAGnosis_report {*diagnosis_report1 diagnosis_report2 ...*}

  An optional switch and one or more strings that specifies the diagnosis report file(s) to be targeted by diagnostic ATPG. By default, the tool uses the diagnosis results from previous diagnosis run. You can also supply more than one diagnosis report for suspects from multiple diagnosis report files are targeted in one diagnosis test generation run. The diagnosis report must be in the default ASCII format.

- -MAX_pattern_count [*number*]

  An optional switch and integer pair that specifies the maximum pattern count the tool generates. The default is no limit. Use when ATPG run time is a concern.

- -TRAnsition

  An optional switch that specifies creating transition test patterns. By default, the transition patterns generated are launch off capture (no_shift_launch).

Scan Chain Failure Diagnosis Arguments

- -DIAGnosis_report {*diagnosis_report*}

  An optional switch and string pair that specifies the diagnosis report file to be targeted by diagnostic ATPG. By default, the tool uses the diagnosis results from previous diagnosis run. Note that only a single diagnosis report is allowed as input for chain failures.

- -CHAIN *chain_name*

  An optional argument and string pair that specifies a single chain.

- -CELL_range *lowerbound upperbound*

  An optional argument and pair of integers that specify the beginning and ending of a range of cells.

- -FAULT_type {stuck_at_0 | stuck_at_1 | slow_to_rise | slow_to_fall | slow | fast_to_rise | fast_to_fall | fast}

  An optional argument and literal pair that specifies the fault type.

create_feature_statistics

Context: patterns -scan_diagnosis

Mode: analysis

Usage

create_feature_statistics

Description

Calculates the root cause deconvolution (RCD) constants from the LDB for RCD diagnosis and analysis.

The tool analyzes the design for all possible diagnosis suspects for certain features in the layout. It determines which bridge pairs, net segments, and cells are tested, and extracts the relevant physical information such as the critical area, via count, and cell instance count for each possible suspect.

You must create the RCD constants statistics for every flat model and pattern combination. To do this, you can process the combinations in parallel in different tool sessions.

RCD analysis in Tessent YieldInsight determines the probability sums for the features across the diagnoses and uses the RCD constants to normalize their weights to account for diagnosis noise.

To use this command, you must have previously loaded your patterns and opened a LDB. Otherwise, the tool issues an error message. The feature statistics are stored in the LDB for later use by Tessent YieldInsight RCD analysis. They are not used during the diagnosis process.

For more information, see “Diagnosis for Root Cause Deconvolution Analysis.”

Arguments

- None

Example 1

The following example loads patterns and opens the layout before calculating the feature statistics.

read_patterns external my_test_patterns.wgl

```
//  Reading WGL input file "my_test_patterns.wgl"
```

open_layout my_layout.db

```
//  DieArea: minx=-2107.000000, miny=-2002.000000, maxx=2107.000000,
maxy=2002.0
00000 in microns
//  Note: Checking layout consistency...
//  Note: Layout Database opened successfully.
```

create_feature_statistics

```
//  Determining feature detection information
```

```
//  10% Done.
//  22% Done.
……
//  100% Done.
//  Determining Open Feature Statistics
//  11% Done.
//  21% Done.
……
//  100% Done.
//  Determining Bridge Feature Statistics
//  13% Done.
……
//  Feature Statistics Calculation Complete. Information is written into
the layout database.
```

Example 2

The following example shows the message that the tool returns when you issue the create_feature_statistics when the feature statistics were previously calculated and stored in the LDB.

create_feature_statistics

```
//  Note: Feature statistics for this flat model and pattern set have
already been calculated and stored in the layout database. There is no
need to perform this operation again.
```

create_flat_model

Context: all contexts

Mode: setup

Usage

create_flat_model

Description

Creates a primitive gate simulation representation of the design. The command also flattens the hierarchy of the design so that the design can be viewed in the DFTVisualizer debug window.

The tool automatically flattens the design hierarchy down to the logically equivalent design when you exit Setup mode. However, there may be times that you would like to access the flattened model without having to exit Setup mode. For example, you may want to add atpg constraints and functions before you exit Setup mode.

If you exit Setup mode and then add atpg constraints and functions, the design rule checker does not have access to those ATPG constraints during the rule checking. If you issue the create_flat_model command in Setup mode and then add those ATPG constraints, the design rule checker has access to them during the rule checking.

Note

If you are preparing a flat model for later use in Tessent Diagnosis, save the flat model immediately after performing ATPG (issuing the create_patterns command) and saving final patterns. For more information, refer to "Preparing the Design Netlist" in the *Tessent Diagnosis User's Manual*.

Example

The following example shows flattening the design to the simulation primitives before adding constraints that the rule checker then uses when you run the design rule checker. The rule checker runs when you first attempt to exit Setup mode

```
create_flat_model
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
set_system_mode analysis
```

The following example sets the system mode to setup, creates a flat model, and opens DFTVisualizer:

```
set_system_mode setup
create_flat_model
open_visualizer
```

Related Commands

write_flat_model
add_atpg_constraints

create_initialization_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Usage

create_initialization_patterns ***RAM_instance_name*** | ***RAM_gate_id#***

Description

Creates RAM initialization patterns and places them in the internal pattern set.

The create_initialization_patterns command creates RAM initialization patterns that write values into the specified RAM. Tessent FastScan places these patterns into the internal pattern set from which you may save them into a file.

You can identify the RAM by its instance name or gate ID number. An error condition occurs if there is not a single RAM gate inside the instance or if the specified gate is not a RAM. An error condition also occurs if the RAM does not have an initialization file, or if the RAM did not successfully pass stability checking (Design Rules A1 and A6).

Tessent FastScan creates the initialization patterns by doing an independent test generation for each valid address which has a non-X state on at least one data line. If the test generation aborts, the command terminates with an error message. The patterns contain a measure PO statement, but all values are X. There may also be an unload statement, but all values are X. If the patterns are re-simulated (as in pattern compression), the tool deletes patterns that do not detect faults. For those the tool does not delete, simulation values replace the Xs in the measure PO statement.

Arguments

- ***RAM_instance_name***

  A string that specifies the instance name of the RAM for which you want to create_initialization_patterns.

- ***RAM_gate_id#***

  An integer that specifies the gate identification number of the RAM for which you want to create_initialization_patterns.

Example

The following example creates RAM initialization patterns for *p1.ram/u1*, places the patterns into the internal pattern set during the ATPG run, and saves the patterns to a pattern file with the name *patfile*:

```
add_write_controls 0 w1
set_system_mode analysis
add_faults -all
create_initialization_patterns p1.ram/u1
create_patterns
write_patterns patfile
```

Related Commands

write_modelfile

create_instance

Context: all contexts

Mode: insertion

Usage

create_instance ***hierInstPath*** **-of_module** ***mod_spec*** [-allow_instance_uniquification] [-instance_uniquification_suffix *string*] [-parameter_list *parameter_value_list*] [-silent]

Description

Instantiates an instance of a module mod_spec inside a design module in the current design.

If the command is successful, this command returns a collection containing the newly created instance.

The pathname to the location must exist in the design up to the leaf level. If the leaf level already exists and the -allow_instance_uniquification switch is specified, Tessent Shell adds a uniquification suffix to the new instance to create a unique instance name. The uniquification suffix defaults to _# where # is replaced by the first available integer starting from 1. You can specify a different uniquification suffix using the -instance_uniquification_suffix option in the create_instance command or in the set_insertion_options command.

Arguments

- ***hierInstPath***

  A required string that specifies the hierarchical path in which the instance is to be created concatenated to the leaf instance name of the new instance. The specified hierarchical path in which the instance is to be created must exist in the design. If an instance of the module to be instantiated already exists in that module, by default the tool uniquifies the new name by adding a "_#" suffix to the instance name. You can use the instance_uniquification_suffix switch to specify a different suffix.

- **-of_module** ***mod_spec***

  A required switch and value pair that specifies the module to be instantiated. mod_spec can be the name of a module or a module object returned by the get_module command.

Note

Currently, any instantiation of parameterized modules can only be done with default values.

- -allow_instance_uniquification

  An optional switch that specifies to automatically uniquify the name of the new instance being instantiated if an instance of the same name already exists in the current design. This feature is very useful when inserting gates to intercept signals. You can always use the same leaf instance name and let the tool resolve conflicts automatically. This use model is illustrated in Examples 2, 3, 4 and 5 in the move_connections command description.

- -instance_uniquification_suffix *string*

  An optional switch that specifies a string to add to the new instance name when an instance of the same name already exists and the -allow_instance_uniquification switch is specified. If this switch is not specified, the tool automatically uniquifies the object using the default string "_#" where # begins at 1 and increments by one until a unique name has been found. The *string* must always end with a # to denote the uniquification integer.

- -parameter_list *parameter_value_list*

  An optional switch that specifies a Tcl list of parameter values when you use the command to create an instance of a parameterized module. The instance uses the supplied list of parameter values. For an example of how to use this switch, refer to "Example 4" on page 662.

  This switch is available only in -rtl mode ("set_context dft -rtl"). For more information, refer to the set_context command.

- -silent

  An optional argument that specifies to not generate an error message under the following condition. When the error is suppressed, no instance is created and the command returns a null collection. When no errors are suppressed, the command returns a collection containing the newly created instance.

  - The hierarchical path above the leaf instance name does not exist in the design.
  - The specified mod_spec is not the name of an existing module.
  - The collection supplied to the -of_module option does not contain a single module object.

Example 1

The following example creates an instance of module ModA called ModA_1 inside instance Block1_I1/Block2_I1. The return value is an instance object by the name of Block1_I1/Block2_I1/ModA_1.

create_instance Block1_I1/Block2_I1/ModA_1 -of_module ModA

```
{Block1_I1/Block2_I1/ModA_1}
```

Example 2

The following example creates two instances of module MUX called MUX inside instance Block1_I1. The tool uniquifies the leaf instance name when a name conflict occurs on the second invocation of the command.

create_instance Block1_I1/MUX -of_module MUX -allow_instance_uniquification

```
{Block1_I1/MUX}
```

create_instance Block1_I1/MUX -of_module MUX -allow_instance_uniquification

```
{Block1_I1/MUX_1 }
```

Example 3

This example creates two instances of module MUX called MUX inside instance Block1_I1. The tool uniquifies the leaf instance name when a name conflict occurs. The get_attribute_value_list command returns the value of the leaf_name attribute on the new instance name.

**get_attribute_value [create_instance Block1_I1/MUX -of_module MUX \
-allow_instance_uniquification] -name leaf_name**

```
{MUX}
```

**get_attribute_value [create_instance Block1_I1/MUX -of_module MUX \
-allow_instance_uniquification] -name leaf_name**

```
{MUX_1}
```

Example 4

This example creates an instance of a parameterized module using a list of parameter values. This example is based on the following Verilog module:

```
module ff(clk,d,q);
   parameter SIZE = 1;
   parameter OTHER = 0;
   input                clk;
   input   [(SIZE-1):0] d;
   output  [(SIZE-1):0] q;
   reg     [(SIZE-1):0] q;
….
}
```

Then the following command

create_instance ff_i3 -of_module ff -parameter_list { SIZE 10 }

creates the following Verilog code:

```
ff #(.SIZE(10), .OTHER(0)) ff_i3(.clk(), .d(), .q());
```

And this command

create_instance ff_i4 -of_module ff -parameter_list [list SIZE 10 OTHER 10]

creates the following Verilog code:

```
ff #(.SIZE(10), .OTHER(10)) ff_i4(.clk(), .d(), .q());
```

create_layout

Context: patterns -scan_diagnosis

Mode: analysis

Usage

create_layout ***layout_database_name*** {**-lef** ***lef_file_name*** … | **-leflist** ***leflist*** } {**-def** ***def_file_name*** ... | **-deflist** ***deflist*** } [-replace] {[-extra_layout_hierarchy *extra_levels_of_hierarchy_in_layout*] | [-extra_design_hierarchy *extra_levels_of_hierarchy_in_design*]} [-threshold *percentage_match*] [-temp_dir *directory_name*]
[-compression {on | off}] [-keep_uncompressed_database] [-verify_only]

Description

Generates a diagnosis tool-compatible Layout Database directory from LEF/DEF input files.

See "Layout-Aware Diagnosis" in the *Tessent Diagnosis User's Manual* for complete information.

For LEF files, you must specify the file containing the layer definitions first followed by any of the MACRO definitions in any order.

The diagnosis tool performs a layout verification of the LEF/DEF files and reports any mismatches to the transcript—see "Layout Verification and Layout Database Creation Process in the *Tessent Diagnosis User's Manual*.

After the layout-verification stage, you can interrupt the Layout Database creation by issuing a **Ctrl-C** in the invocation shell. You can subsequently use the report_layout_rules command to obtain details on the layout rule violations and use this information to correct errors in LEF/DEF files, providing the correct LEF/DEF files and/or add any missing LEF/DEF files to the list provided to the create_layout command. Following this, you then use the create_layout command to determine if there are any additional issues. Use this method in iterative fashion to correct any problems with the LEF/DEF before creating the Layout Database.

Note

For maximum efficiency, you should create or use Layout Databases with the data on your machine's local disk.

Arguments

- ***layout_database_name***

  A required string that specifies the name of the Layout Database directory that diagnosis creates from the LEF/DEF input.

- **-lef** ***lef_file_name*** …

  Space-separated name(s) of the LEF file(s).

- **-leflist *leflist***

  A TCL list of the LEF file(s).

- **-def *def_file_name* …**

  Space-separated name(s) of the DEF file(s).

- **-deflist *deflist***

  A TCL list of the DEF file(s).

- -replace

  An optional switch for overwriting an existing file.

- -extra_layout_hierarchy *extra_levels_of_hierarchy_in_layout*

  An optional switch and string pair that removes extra levels of layout hierarchy such that the design hierarchy and layout hierarchy match. You can only specify this switch once, otherwise the tool issues an error and exits.

  You use this switch if your design is a subset of a larger layout hierarchy. You can specify multiple levels of hierarchy in one string with no spaces. Figure 7-9 illustrates this usage.

Figure 7-9. Extra Layout Hierarchy Example

In the case of Figure 7-9, the following command removes the hierarchy from the LEF/DEF net, pin names, and so forth before matching with the design name:

create_layout *layout_database_name* -lef *lef_file* -def *def_file* -extra_layout_hierarchy inst1

- -extra_design_hierarchy *extra_levels_of_hierarchy_in_design*

  An optional switch and string pair removes extra levels of design hierarchy such that the layout hierarchy and design hierarchy match. You can only specify this switch once, otherwise the tool issues an error and exits.

  You use this switch if your layout is a subset of a larger design hierarchy. You can specify multiple levels of hierarchy in one string with no spaces. Figure 7-10 illustrates this usage.

Figure 7-10. Extra Design Hierarchy Example

In the case of Figure 7-10, the following command removes hierarchy from a design pin, net name, and so forth before matching with layout:

create_layout *layout_database_name* -lef *lef_file* -def *def_file* -extra_design_hierarchy inst1

Note

The -EXTRA_DESign_hierarchy and -EXTRA_LAYout_hierarchy switches are mutually exclusive, and the tool issues an error if you specify both.

- -threshold *percentage_match*

  An optional switch and integer pair specifies the minimum percentage match threshold required to successfully complete a layout verification of the LEF/DEF files, and subsequent creation of the layout database. The default threshold value is 85 percent. The following command sets the required layout match threshold to 92%:

  create_layout design.layout -lef lef_input.lef -def def_input.def -threshold 92

- -temp_dir *directory_name*

  In some cases, Tessent Diagnosis must update the Layout Database (for example, if you use the -verify switch). Due to the fact that the compressed Layout Database is a read-only database, Tessent Diagnosis automatically uncompresses, updates, and re-compresses the Layout Database. By default, the temporary uncompressed LADB is stored into the same location where the compressed Layout Database is located; if you have limited disk space in this location, then use the -TEmp_dir switch and string pair to specify an alternative location.

  See "Layout Database Compression and Decompression" in the *Tessent Diagnosis User's Manual* for complete information.

- -compression {on | off}

  An optional switch and literal that controls whether the tool compresses the Layout Database during database creation. The default is OFF. Specify ON to create a compressed Layout Database.

  See "Layout Database Compression and Decompression" in the *Tessent Diagnosis User's Manual* for complete information.

- -keep_uncompressed_database

  An optional switch that specifies that the tool retain a copy of the uncompressed Layout Database as well as a compressed version of the Layout Database.

- -verify_only

  An optional switch that enables LEF/DEF design verification.

Example 1

In the following example, the diagnosis tool creates a Layout Database (*design.layout*) from multiple LEF files and DEF files:

```
create_layout design.layout -lef lef_input01.lef lef_input02.lef -def def_01.def def_02.def
```

Example 2

In the following example, Tessent Diagnosis creates a Layout Database (*design.layout*) from a LEF file (*lef_input.lef*) and four DEF files (*a.def, b.def, c.def, d.def*).

```
create_layout design.layout -lef lef_input.lef -def a.def b.def c.def d.def
```

create_module

Context: all contexts

Mode: insertion

Usage

create_module ***module_name*** [-language {verilog | vhdl}] [-in_library *library_name*] [-vhdl_architecture *vhdl_architecture*] [-silent]

Description

Creates a new design module with no ports.

Ports can then be added to this new design module using the create_port command.

The create_module command returns a collection of one module object where the module is a newly created module.

Arguments

- ***module_name***

  A required string that specifies the name of the module to create.

- -language verilog | vhdl

  An optional switch and literal pair that specifies which language (Verilog or VHDL) to use when creating the module. The language defaults to Verilog when this option is not specified. The -language option is only allowed in the rtl context.

- -in_library *library_name*

  An optional switch and string pair that specifies in which library to create the module. The specified library_name must be a library name previously defined with the set_logical_design_libraries command. When the -in_library option is not specified, the module is created inside the default library which is also specified using the set_logical_design_libraries command. The -in_library option is only allowed in the rtl context.

- -vhdl_architecture *vhdl_architecture*

  An optional switch and string pair that specifies the name of the architecture to use for a created VHDL module. When -vhdl_architecture is not specified and -language is specified as vhdl, the created architecture is called struct. You cannot specify -vhdl_architecture unless -language is specified as vhdl. The -vhdl_architecture option is only allowed in the rtl context.

- -silent

  An optional switch that suppresses the error that is normally generated if module_name already exists. A null collection is returned when an error is suppressed.

Example 1

The following example creates a module called mytop and makes it the current module so that other modules can be instantiated in it.

set_ context dft -no_rtl
set_system_mode insertion
create_module mytop

```
{mytop}
```

set_current_design mytop

Example 2

The following example creates a module called myblock and appends the newly created module object to a collection referenced by the Tcl variable called created_modules.

append_to_collection created_modules [create_module myblock]

```
{myblock}
```

Example 3

The following example creates a VHDL module inside library lib1 with the default vhdl architecture struct. Notice how the get_modules command is used to report its attribute as report_attribute only looks for modules in the default library

create_module M1 -in_library lib1 -language vhdl

```
{M1}
```

report_attributes [get_modules M1 -in_library lib1]

```
Attribute Definition Report

Attributes defined for object 'M1':
Name                Value   Inheritance
-----------------   ------  -----------
file_path_name              -
is_created          true    -
is_modified         false   -
is_unsaved          true    -
is_valid            true    -
language            vhdl    -
library_name        lib1    -
line_number         0       -
master_name         M1      -
name                M1      -
object_type         module  -
type                design  -
vhdl_architecture   struc   -
```

create_net

Context: all contexts

Mode: insertion

Usage

create_net ***hier_net_name*** [-ascending] [-silent]

Description

Creates a net inside an instance of a design module in the current design.

This command returns a collection of created net objects. This command returns one object for each bit of a bus with the left bit first and the right bit last.

Arguments

- ***hier_net_name***

  A required string that specifies the path to the instance in which the net will be created, and the leaf name of the net to be created in the module. If the net name is a bus, this command creates one net for each bus bit, beginning with the left-most bit of the bus and ending with the right-most. The specified hierarchical path in which the net is to be created must exist in the design.

- -ascending

  An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index; otherwise, the tool uses the “downto” range direction type. An error is generated if you specify this option and the left index is larger than the right index, or if the object name is not a bus. The -ascending option is only allowed in the rtl context.

- -silent

  An optional argument that specifies the suppression of an error given one of the situations below. The command returns a null collection when an error is suppressed.

  - The hierarchical path of the net name specified does not exist in the design
  - The net already exist in the design

Example

The following example creates a two-bit bus net called A inside instance u1.

create_net u1/A[4:5]

```
{u1/A[4] u1/A[5]}
```

create_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Usage

create_patterns [-OVerride_user_settings | -NO_AUto]
[-Compaction_effort {Low | High | Maximum | *integer*}] [-NO_Analyze]
[-COVerage_effort { Low | High }] [-NO_REDundancy_analysis]
[-NO_TERMINATE_ineffective_atpg] [-PATterns_per_pass *integer*]

Description

Performs automatic high-speed test generation and pattern compression.

This command is the recommended way to produce high quality, efficient, test pattern sets in the shortest possible time.

This is a multiprocessing command for ATPG. For more information about multiprocessing, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual*.

The create_patterns command uses the built-in expert system, ATPG Expert, to create patterns. ATPG Expert analyzes the design and DRC and may modify tool settings to optimize test patterns for coverage, pattern count, and run time. By default, ATPG Expert only optimizes settings that have not been explicitly specified; it does not change user-specified settings. If you want ATPG Expert to also optimize user-specified settings, use the -override_user_settings switch. Additionally, a statistics report is automatically displayed. The create_patterns command displays the following statistics:

- Number of patterns simulated
- Test coverage
- Number of faults detected
- Number of faults remaining in the fault list (undetected)
- Number of effective patterns
- Number of test patterns
- Number of redundant, untestable, and aborted faults

  Occasionally, the display includes a line with three or four numbers separated by slashes (/). These numbers are, from left to right, the cumulative number of redundant (RE), ATPG_untestable (AU), and aborted faults. Aborted faults are separated into ATPG aborts (AAB) and EDT aborts (EAB) depending on whether compression is on. The sum of AAB and EAB aborts equal the total number of aborts.

  Example transcript without compression (these numbers are shown in bold font):

```
//#patterns test     #faults #faults   #eff.   #test    process    RE/AU/AAB
//simulated coverage in list detected patterns patterns CPU time
//   ---      ---     ---      ---      ---      ---    5.79 sec   0/40868/57

//    64     74.10%  135463  413980      63      63     14.73 sec
```

Example transcript with compression (these numbers are shown in bold font):

```
//#patterns   test   #faults #faults   #eff.   #test    process    RE/AU/AAB/EAB
//simulated coverage in list detected patterns patterns CPU time
//   ---     ------    ---     ---      ---      ---    5.79 sec   0/40868/27/30
//    64     74.10%  135463  413980      63      63     14.73 sec
```

At the end of the create_patterns run, the tool automatically performs redundant fault identification, which is equivalent to running the identify_redundant_faults command. If, however, you set any ATPG limit (for example, test coverage limit, run time limit, or pattern limit), then the tool does not perform redundant fault identification.

You should use the create_patterns command, review the transcript for any suggested command or setting changes, and implement the ones that help you achieve your test goals. Be aware that some of the suggestions have trade-offs (for example, greater run time in exchange for fewer test patterns); the merits of the trade-offs depend on your particular test requirements.

Note

When you perform compression analysis, the final order of scan cells in each scan chain in the design is not known. The order of the scan cells used as deterministic bits in the test cube impacts ATPG results. If many of the deterministic bits are clustered in consecutive cycles, more EDT_ABORT faults may appear because the clustered deterministic bits may not be compressed. When this occurs, ATPG test coverage may drop.

During compression analysis, the tool assumes the scan chains are organized in a balanced way based on an existing scan cell ordering. However, in the real design, scan cells may be in an arbitrary position depending on which scan stitching tool was used. If the clustering of deterministic bits occurs during compression analysis but not in the real design or if the clustering occurs in the real design but not in compression analysis, a discrepancy in the ATPG results may occur.

Note that you can use the add_faults command to define the scope of the create_patterns command. For more information, refer to “Example 3” on page 675.

The CPU time the tool reports is the time local to the command. If the command has multiple phases, then the reported CPU time is with respect to the beginning of that phase.

Arguments

- -OVerride_user_settings

  An optional switch that enables ATPG Expert to override user-specified settings if necessary to create an optimal test pattern set.

- -NO_AUto

  An optional switch that disables use of ATPG Expert to create patterns. During test generation, the default settings are used for those settings that have not been explicitly specified.

- -Compaction_effort {Low | High | Maximum | *integer*}

  An optional switch that specifies how much effort to spend trying to reduce the pattern count:

  Low

  Specifies a faster run time but a higher pattern count than the High option.

  High

  Specifies a longer run time but a smaller pattern count than the Low option. Use High when generating production patterns because this can significantly reduce test time and test data volume. This option usually gives the best results and is the default.

  Maximum

  Enables maximum tool effort to reduce pattern count. This option significantly increases run time and should be used only when absolutely necessary. Integer value 10 or 100 should be used before using this option due to the significantly long run time.

  integer

  A positive integer value that specifies compaction effort as follows:

  0 = Low
  1 = High (usually give the best results)
  n = The tool works *n* times harder than High

  As a general guide, when *n*=10, the run time increase is small, and the pattern count can be slightly better. When *n*=100, pattern reduction can be similar to Maximum, while the run time can be lower than Maximum. Differences in design complexity and size can affect which integer value provides the desired trade-off between pattern counts and run time.

  Note that you can significantly reduce the run time caused by higher integer values by using multiprocessing. For more information about multiprocessing, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual.*

- -NO_Analyze

  An optional switch that skips the analysis of test generation problems. Normally, before test generation, create_patterns checks for bus contention and whether ATPG restrictions and constraints can be satisfied. If these checks reveal potential test generation problems, an error message displays and the command terminates. If you want the analysis to be ignored and to proceed with test generation, reissue the command with this switch.

Note

Because this switch prevents normal analysis, all faults can be targeted, and ATPG effort expanded, yet without generating patterns. The extra effort may also give the appearance that the tool is stuck. Use this switch only in special cases when the risks are acceptable.

- -COVerage_effort { Low | High }

  An optional switch that improves ATPG test coverage. When set to High, the tool retargets aborted faults and uses dynamic learning during retargeting. Note that using this setting can result in significantly higher run times in some cases. By default, the tool does not retarget aborted faults.

  Using this switch may increase the ATPG run time.

- -NO_REDundancy_analysis

  An optional switch that, for ATPG using Named Capture Procedures, omits the redundancy identification analysis that follows pattern generation. Using this switch allows you to generate patterns faster. However, the test coverage calculations are less accurate without the redundancy identification analysis.

- -NO_TERMINATE_ineffective_atpg

  An optional switch that disables a feature that terminates the ATPG session after the patterns are no longer efficient at detecting faults. Note that using this switch results in a longer run time and may generate many additional patterns to detect very few faults.

- -PATterns_per_pass *integer*

  An optional switch and positive integer pair that specifies how many patterns to create and simulate in each pass. The integer value must be between 1 and 64. By default, the tool creates and simulates 64 patterns in each pass. When the value is 1, the tool generates and simulates every pattern, and so on. The switch affects only the current create_patterns session.

  The potential benefit of using a smaller integer value rather than the default 64 is better pattern count because ATPG is less likely to add non-essential faults into a pattern. However, when the value is small, the overall run time is likely to increase due to excessive fault simulation. Furthermore, a small value can reduce the run-time efficiency of multithreading and distributed ATPG.

  A smaller value is appropriate if the expected pattern count is small. A typical scenario for using a small integer value is IDDQ pattern generation, where you should use “create_patterns -patterns_per_pass 1” with “set_atpg_limits -pattern_count *n*” for creating *n* IDDQ patterns. You can use the -compaction_effort option with -patterns_per_pass to maximize the effectiveness of each pattern, but at the expense of additional run time.

Example 1

The following example creates, through ATPG Expert, an internally-stored set of optimally compact patterns for the entire netlist that can be saved using the write_patterns command.

ATPG Expert automatically decides the best setup (for example, sequential depth) for the design.

```
set_system_mode analysis
create_patterns
```

Example 2

The following example also creates an internally-stored set of compact patterns; however, ATPG Expert has been disabled. In this case, you need to specify by which sequential depth the pattern is created. The -sequential 2 switch means there are up to two clock pulses between scan loads. The patterns can be saved using the write_patterns command.

```
set_system_mode analysis
set_pattern_type -sequential 2
create_patterns -no_auto
```

Example 3

The following example creates patterns only for the specific block specified by the add_faults command:

```
set_system_mode analysis
add_faults /blockA/blockB
create_patterns
```

create_pin

Context: all contexts

Mode: insertion

Usage

create_pin ***hierPinName*** [-direction input | output | inout] [-ascending] [-silent]

Description

Creates a pin on an instance of a design module.

If –auto_uniquify_edited_modules is On, the module is first uniquified before creating a pin on the specified instance. If –auto_uniquify_edited_modules is Off, the pin is created on the module and all instances of the module get the newly created pin.

This command returns a collection of the pin objects created; if hierPinName is a bus, this command returns a collection with one pin object for each bus bit, beginning with the left-most bit of the bus and ending with the right-most.

Arguments

- ***hierPinName***

  A required string that specifies the hierarchical path of the pin to be created concatenated to the leaf pin name. The specified hierarchical path of the pin to be created must exist in the design.

- -direction input | output | inout

  An optional switch and literal pair that specifies the direction of the newly created pin. An input pin is created by default when this option is omitted.

- -ascending

  An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index; otherwise, the tool uses the “downto” range direction type. An error is generated if you specify this option and the left index is larger than the right index, or if the object name is not a bus. The -ascending option is only allowed in the rtl context.

- -silent

  An optional argument that specifies to not generate an error message if the specified hierPinName already exists or when the hierarchical part of the specified name is not an existing instance within the current design. When an error is suppressed, the command returns an empty collection.

Example

The following example creates a 5-bit bus input pin called A on the instance u1. The command returns a collection of newly created pin objects.

create_pin u1/A[5:1]

```
{u1/A[5] u1/A[4] u1/A[3] u1/A[2] u1/A[1]}
```

The following example introspects the direction attribute of the four newly created pin objects.

get_attribute_value_list [create_pin u1/C[3:0] -direction output] -name direction

```
{output output output output}
```

Related Commands

get_icl_pins

create_port

Context: all contexts

Mode: insertion

Usage

create_port ***port_name*** [-on_module *obj_spec*] [-direction input | output | inout] [-ascending] [-silent]

Description

Creates a port on the specified design module.

By default, this command creates a port on the design module in the current design, If you specify the -on_module argument, this command creates a port on the module specified in *obj_spec*.

This command returns a collection of the port objects created; if port_name is a bus, this command returns a collection with one port object for each bus bit, beginning with the left-most bit of the bus and ending with the right-most.

If the specified port already exists the tool generates an error. You can specify the -silent switch to instruct the tool not to generate an error.

Arguments

- ***port_name***

  A required value that specifies the name of the port to be created. Bus ports must be created with a single create_port command where port_name includes the required bus range.

- -on_module *obj_spec*

  A required switch and value pair that specifies the module to which the port is to be added. The *obj_spec* can be the name of a module or a module object returned by the get_module command. If the -on_module switch is not specified, this command adds the port to the current design which is the module specified by the set_current_design command. You cannot create a port on a module that was read in from a file and that is not instantiated inside the current design. It is possible to create ports on modules created with the create_module command.

- -direction input | output | inout

  An optional switch and literal pair that specify the direction of the newly created port. An input port is created when this option is omitted.

- -ascending

  An optional switch that specifies the range direction type for a VHDL bus port. By default, the range direction type is inferred as “downto” when the left index is larger than the right index, and as “to” when the left index is smaller than the right index. You use this switch to specify that the VHDL port notation is “to” when the left index is equal to the right index; otherwise, the tool uses the “downto” range direction type. An error is generated if you

specify this option and the left index is larger than the right index, or if the object name is not a bus. The -ascending option is only allowed in the rtl context.

- -silent

  An optional argument that specifies to not generate an error message if the specified port_name already exists. When an error is suppressed, the command returns an empty collection.

Example 1

The following example creates a 5-bit bus input port called A on the module that is the current design. The command returns a collection of the newly created port objects.

create_port A[5:1]

```
{A[5] A[4] A[3] A[2] A[1]}
```

Example 2

The following example creates a scalar output port called B on module ModB.

create_port B -on_module ModB -direction output

```
{B}
```

Example 3

The following example creates a 4 -bit bus output port called C on the current design and uses the get_attribute_value_list command to query the direction attribute of the newly created port objects.

get_attribute_value_list [create_port C[3:0]] -name direction

```
{input input input input}
```

Related Commands

delete_ports

get_icl_ports

delete_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_atpg_constraints {***pin_pathname*** | ***gate_ID#*** | {***function_name*** | {**-Cell** ***cell_name*** {***pin_name***…}}}… [-Instance {*object_expression*…}] [-MODUle {*module_name* …}]}… | **-All**

Description

Removes state restrictions from the specified pins. You define pin restrictions by using the add_atpg_constraints command.

If you change ATPG constraints, create patterns with those changed constraints, and then compress patterns, all patterns not meeting the new constraints are rejected. This can cause the good patterns created with the old constraints to be rejected; therefore, use the delete_atpg_constraints command to remove all ATPG constraints before compressing the pattern set.

Arguments

- ***pin_pathname***

  A repeatable string specifying the pathname of the pin from which to remove any ATPG pin constraints.

- ***gate_ID#***

  A repeatable integer specifying the gate identification number of the gate from which to remove any ATPG pin constraints.

- ***function_name***

  A repeatable string specifying the name of a function created with the add_atpg_functions command and from which to remove any ATPG pin constraints.

- **-Cell** ***cell_name*** {***pin_name***}

  A repeatable switch and string pair that removes ATPG constraints from the specified pin on the DFT library cell. You can repeat the *pin_name* argument if there are multiple pins or nets on a cell that have ATPG constraints you need to remove.

- -Instance *object_expression*

  An optional switch and repeatable string pair that removes ATPG constraints inside the specified list of instances. You can use regular expressions, which may include any number of embedded asterisk (*) and/or question mark (?) wildcard characters. You can only use this switch when using the -Cell option or when a function name is specified.

- -MODUle *module_name*

  An optional switch and repeatable string pair that removes the ATPG constraints inside all instances of the specified module.

- **-All**

  A switch that removes all current, user-defined ATPG constraints from all objects.

Example 1

The following example creates two user-defined ATPG pin constraints, runs the ATPG process, removes all ATPG constraints, and then compresses the pattern set:

```
set_system_mode analysis
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
create_patterns
delete_atpg_constraints -all
compress_patterns
```

Example 2

The following Tessent FastScan example shows how to use wildcards.

```
add_atpg_constraints 1 -cell mux21 Y -ins uALU/*/ix184 .
report_atpg_constraints .
```

```
1 dynamic /uALU/u3/ix184/Y (4400) .
1 dynamic /uALU/u2/ix184/Y (4406) .
1 dynamic /uALU/u1/ix184/Y (4412) .
```

```
delete_atpg_constraints -cell mux21 Y -ins uALU/u1/* .
report_atpg_constraints .
```

```
1 dynamic /uALU/u3/ix184/Y (4400) .
1 dynamic /uALU/u2/ix184/Y (4406) .
```

Related Commands

add_atpg_constraints
add_atpg_functions
report_atpg_constraints

delete_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_atpg_functions ***function_name***... | **-All**

Description

Removes the specified function definitions.

The delete_atpg_functions command lets you delete_atpg_functions defined with the add_atpg_functions command. You cannot remove an ATPG function if an ATPG constraint is currently using that function. If you attempt to remove an in-use function, the tool generates an error. Therefore, if you need to delete an in-use ATPG function, you must first remove all the associated ATPG constraints using the delete_atpg_constraints command; then you can remove the ATPG function.

You can display a list of the current ATPG functions that the tool is using as ATPG constraints by using the report_atpg_constraints command.

Arguments

- ***function_name***

  A repeatable string that specifies the names of the ATPG functions that you want to delete.

- **-All**

  A switch that removes all ATPG function definitions.

Example

The following example creates two user-defined ATPG functions, one user-defined ATPG constraint, displays the currently-in-use ATPG constraints, and then removes one of the inactive ATPG functions:

```
add_atpg_functions and_b_in And /i$144/q /i$141/q /i$142/q
add_atpg_functions select_b_in select /i$144/q /i$142/q
add_atpg_constraints 0 /i$135/q
report_atpg_constraints

0 /$135/Q (23)

delete_atpg_functions and_b_in
```

Related Commands

add_atpg_functions
delete_atpg_constraints
report_atpg_constraints
report_atpg_functions

delete_bist_capture_ranges

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_bist_capture_ranges ***capture_proc_name*** | **-All**

Description

Specifies that the tool no longer uses a particular named capture procedure when generating BIST patterns.

Arguments

- ***capture_proc_name***

  A required string that specifies the name of the capture procedure.

- **-All**

  A switch that specifies that the tool no longer use any named capture procedures when generating BIST patterns.

Related Commands

add_bist_capture_range

report_bist_capture_ranges

delete_black_boxes

Context: all contexts

Mode: setup

Usage

delete_black_boxes **-Instances** [*ins_pathnames*] | **-Module**s[*module_names*] | **-All**

Description

Undoes the effect of the add_black_boxes command.

For a module that was originally modeled, removing the effect of the add_black_boxes command reinstates the original model. Specified tied values are no longer set on the output pins. For a module that was empty or undefined in the input netlist, the output pins revert to the default tied value of X.

Note

The tool releases the flattened model if one exists at the time you issue this command.

Arguments

- **-Instances** [*ins_pathnames*]

  A switch that specifies for the tool to undo the effect of the add_black_boxes command on all instances specified by the ins_pathnames argument. The ins_pathnames argument can be an instance, a Tcl list of instances, or a collection of instances. If you do not specify the ins_pathname, the tool undoes the effect of the add_black_boxes command on all instance-based blackboxes.

- **-Modules** [*module_names*]

  A required switch that specifies for the tool to undo the effect of the add_black_boxes command on all instances of modules specified by the module_names argument. The module_names argument can be an instance, a Tcl list of instances, or a collection of instances. If you do not specify the module_names argument, the tool undoes the effect of the add_black_boxes command on all module-based blackboxes.

- **-All**

  A required switch that specifies for the tool to undo the effect of the add_black_boxes command on all blackboxes.

Example 1

The following example adds the black box for module “core” then undoes all blackboxes that were defined.

```
add_black_boxes -modules core 1
delete_black_boxes -all
```

Example 2

The following example deletes blackboxes for the collection of modules returned by the get_modules command. The get_modules command returns only those modules that have been marked by the user with the user-defined attribute mark_black_box.

```
delete_black_boxes -modules [get_modules -filter mark_black_box]
```

Related Commands

delete_browser_data

Context: all contexts

Mode: setup, analysis

Usage

delete_browser_data {{**Gates** | **Primitives**} | {**Drc** [-All_fails | *rule_id*]} |
{**FAults** [-ALl | -Total | -Undet | *fault_class*]} |
F_coverage | **T_coverage** | **Relevant_Test_Coverage | Loss_TC |**
ATpg_effectiveness | **ALl}** [-Tab {Hierarchy | Library | Clocks}]

Description

Removes data from the active tab of the DFTVisualizer Browser window.

You use the -*Tab* switch to specify to remove the data column from a tab that is not the active tab.

Multiple arguments can be used in one delete_browser_data command.

Arguments

- **Gates**

  Required literal that deletes the design level gates listed for each instance.

- **Primitives**

  Required literal that deletes the primitive level gates listed for each instance.

- **Drc**

  Required literal that deletes DRC violation information from the Browser window. By default, all DRC violation information is deleted. Options include:

  rule_id
  String that specifies a design rule to delete violation information for. The *rule_id* must be the exact identification (ID) shown at the top of the column to delete. For a complete list of rule violation IDs, refer to the "Design Rule Checking" chapter.

- **FAults**

  Required repeatable literal that deletes fault information from the Browser window. By default all fault information is deleted. Options include:

  -Total
  Switch that deletes the display of total faults for all classes.

  -Undet
  Switch that deletes the display of numbers of undetected (UD) faults.

  fault_class
  String that specifies a fault_class to delete faults for. The *fault_class* must be the character string shown at the top of the column to delete. For a summary of available fault classes, refer to the report_faults command.

-ALl
Switch that specifies to delete all fault classes that are currently displayed. This switch is valid in the Hierarchy and Clocks tabs of the Browser window.

- **F_coverage**

  Required literal that deletes all the fault coverage data from the display.

- **T_coverage**

  Required literal that deletes all the test coverage data from the display.

- **Relevant_Test_Coverage**

  Required literal that deletes the test coverage for each submodule after untestable faults have been added/deleted from test coverage calculations.

- **Loss_TC**

  Required literal that deletes the undetected faults in an instance displayed as a percentage of the testable faults in the entire design.

- **ATpg_effectiveness**

  Required literal that deletes all the ATPG effectiveness data from the display.

- **ALl**

  Required switch that deletes all data from the display.

- -Tab {Hierarchy | Library | Clocks}

  Optional switch and literal that specifies the tab in the Browser window from which the column is to be deleted. By default, the delete_browser_data command removes data from the active window. You can use this switch to specify to remove the data column from a tab that is not the active tab.

Examples

The following example adds three columns to the active tab of the Browser window, and then removes the column that shows the number of C5 DRC violations:

```
add_browser_data drc c3 drc c5 drc c6
delete_browser_data drc c5
```

Related Commands

add_browser_data

delete_capture_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_capture_handling {***object***... | **-All**} [-SInk | -SOurce]

Description

Removes the special data capture handling for the specified objects.

When you remove the special data capture handling, the default handling resumes. The default data capture handling specifies that the source elements pass on the values from the previous (not the current) clock cycle. When using the delete_capture_handling command, you must specify either an object name or all objects.

Arguments

- ***object***

  Specifies the object(s) for which you want the tool to remove any special data capture handling. The following lists the valid choices for the *object* argument:

  gate_id# — A repeatable integer that specifies the gate identification numbers of the objects. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

  pin_pathname — A repeatable string that specifies the name of a pin within the design.

  instance_name — A repeatable string that specifies the name of an instance within the design.

  -Cell *cell_type* — A repeatable switch and string pair that specifies the name of a cell.

- **-All**

  A switch that removes all special data capture handling.

- -SInk

  An optional switch specifying that the *object* argument is a termination point. This is the default behavior for the command.

  If you use this switch in combination with the -All switch, the tool removes all special data capture handling on all the sink elements.

- -SOurce

  An optional switch specifying that the *object* argument is an origination point for data capture.

  If you use this switch in combination with the -All switch, the tool removes all special data capture handling on all the source elements.

Example

The following example changes the data capture handling of two specific gates and then removes one of those changes.

```
add_capture_handling new 1158 1485 -source
delete_capture_handling 1158
```

Related Commands

delete_capture_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Usage

delete_capture_procedures {**-All** | **-Created_capture_procedures** | **-Loaded_capture_procedures** | **-Disabled** | ***capture_procedure_name***...}

Description

Removes the specified capture procedures from internal memory.

The delete_capture_procedures command deletes all or specific named capture procedures from the internal tool memory. A named capture procedure used by the current pattern set cannot be deleted.

Arguments

- **-All**

  A switch that deletes all the named capture procedures.

- **-CReated_capture_procedures**

  A switch that deletes all the named capture procedures automatically created by the tool.

- **-LOaded_capture_procedures**

  A switch that deletes all the named capture procedures loaded using the read_procfile command or from procedure files associated with the scan group definition.

- **-DIsabled**

  A switch that deletes all the disabled named capture procedures.

- ***capture_procedure_name***

  A repeatable string that specifies a named capture procedure to delete.

Example 1

The following example deletes all capture procedures.

```
delete cap proc -All
```

Example 2

The following example removes the capture procedure named *user_capture_proc1*.

```
delete cap proc user_capture_proc1
```

Related Commands

create_capture_procedures
report_capture_procedures
set_capture_procedures

delete_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

delete_cdp_test ***test_name***

Description

Deletes a test and its associated test patterns from the CDP.

Arguments

- ***test_name***

  A required string that specifies the name of the test that you want to delete.

Example

The following example deletes test1 from the CDP.

```
delete_cdp_test test1
```

Related Commands

add_cdp_test

delete_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_cell_constraints **-All** | ***pin_pathname*** | {***chain_name cell_position***} | {**-Drc C6**} | {**-CHain** ***chain_name***} | {**-CLock** ***clock_name***}

Description

Removes constraints placed on scan cells.

The delete_cell_constraints command deletes the constraints placed on scan cells using the add_cell_constraints command. You can specify a scan cell by using either a pin pathname or a position in a scan chain.

Arguments

- **-All**

  A switch that, in Setup mode, specifies to delete all constraints from all scan cells. In analysis mode (Tessent FastScan and Tessent TestKompress only), it specifies to delete all cell constraints that were added in non-Setup modes.

- ***pin_pathname***

  A string that specifies the name of an output pin which directly connects to a scan memory element (you can only specify output pins of buffers and inverters). Valid in Setup mode only.

- ***chain_name cell_position***

  A string and integer pair that specifies the name of a currently-defined scan chain and the position of the cell in the scan chain. The *cell_position* is an integer where 0 is the scan cell closest to the scan-out pin. Valid in Setup mode only.

- **-Drc C6**

  A switch and literal pair that specifies to delete all cell constraints added by “add_cell_constraints -drc c6”. Valid in analysis mode only.

- **-CHain** ***chain_name***

  A switch and string pair that specifies to delete all cell constraints added by the -Chain argument to the add_cell_constraints command. Valid in analysis mode only.

- **-CLock** ***clock_name***

  A switch and string pair that specifies to delete all cell constraints added by the -Clock argument to the add_cell_constraints command. Valid in analysis mode only.

Example

The following example deletes an incorrectly added cell constraint placed on a scan cell:

```
add_clocks 1 clock1
add_scan_groups group1 proc.g1
add_scan_chains chain1 group1 scanin1 scanout1
add_scan_chains chain2 group1 scanin2 scanout2
add_cell_constraints chain1 5 c0
add_cell_constraints chain2 3 c1
delete_cell_constraints chain2 3
add_cell_constraints chain2 4 c1
report_cell_constraints
```

Related Commands

add_cell_constraints

report_cell_constraints

delete_cell_library

Context: unspecified, all contexts

Mode: setup

Usage

delete_cell_library

Description

Removes all current cell libraries, the current design including the flattened model, and all tool data that is design-specific.

This command also closes any open DFTVisualizer windows.

When this command is deleting a flat model, and that flat model was saved with a list of enabled/disabled commands, then the restriction on the disabled commands is removed. In other words, all commands allowed in the tool will be enabled for the next design.

Arguments

None

Example

The following example removes all current cell libraries:

```
delete_cell_library
```

Related Commands

delete_design
read_cell_library
read_flat_model
read_verilog
set_current_design
set_design_macros

delete_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

delete_cell_models ***dftlib_model***… | {**-Type** {**INV** | **And** | **Buf** | **OR** | **NAnd** | **NOr** | **Xor** | **Mux** | **Scancell** | **DFf** | **LATCH**}} | **-All**

Description

Specifies the name of the DFT library cell that the tool is to remove from the active list of cells that the user can access when adding test points or that the tool can access when inserting test logic.

You originally added the cells to the active list with either the add_cell_models command or with the *cell_type* library attribute. If you remove a cell model from the active list, you only remove the cell from that list and do not change the DFT library.

If you accidently delete a DFT library cell from the active list with the delete_cell_models command, you can add the specified cell back into the active list with the add_cell_models command.

Arguments

- ***dftlib_model***

  A repeatable string that specifies the names of the particular DFT library models that you want the tool to remove from the active list.

- **-Type INV** | **And** | **Buf** | **OR** | **NAnd** | **NOr** | **Xor** | **Mux** | **Scancell** | **DFf** | **LATCH**

  A switch and argument pair that specifies the cell model type of all DFT library models that you want the tool to remove from the active list. The valid cell model types are as follows:

  INV — A literal that specifies a one-input inverter gate.

  And — A literal that specifies a two-input AND gate.

  Buf — A literal that specifies a one-input buffer gate.

  OR — A literal that specifies a two-input OR gate.

  NAnd — A literal that specifies a two-input NAND gate.

  NOr — A literal that specifies a two-input NOR gate.

  Xor — A literal that specifies a two-input exclusive OR gate.

  Mux — A literal that specifies a 2-1 multiplexer.

  Scancell — A literal that specifies a mux-scan D flip-flop.

  DFf — A literal that specifies a D flip-flop.

  LATCH — A literal that specifies a D latch.

- **-All**

  A switch that removes all cell models from the active list, including those tagged in the DFT library with the *cell_type* attribute. This switch does not change the contents of the DFT library, only the active list within the tool.

Examples

The following example removes a DFT library model from the active list:

```
add_clocks 0 clk
set_test_logic -set on -reset on
set_system_mode analysis
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux s a b
add_cell_models nor2 -type nor
delete_cell_models or2
insert_test_logic
```

Related Commands

add_cell_models
report_cell_models
set_test_logic

delete_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_chain_masks ***chain_name***... | **-All**

Description

Removes chain masks from the specified scan chains.

The delete_chain_masks command deletes chain masks from the specified scan chains defined with the add_chain_masks command. You can delete the definitions of specific chain name or all chains.

Arguments

- ***chain_name***

  A repeatable string that specifies the names of the chain mask definitions that you want to delete.

- **-All**

  A switch that deletes all chain mask definitions.

Example

The following example defines two chain masks then deletes all chain masks:

```
add_chain_masks chain2 chain3
delete_chain_masks -all
```

Related Commands

add_chain_masks

report_chain_masks

delete_clocks

Context: all contexts

Mode: setup

Usage

delete_clocks ***primary_input_pin***... | **-All**

Description

Removes primary input pins from the clock list.

The delete_clocks command deletes primary input pins from the clock list. If you delete an equivalence pin, the command also deletes all of the equivalent pins from the clock list.

Arguments

- ***primary_input_pin***

  A repeatable string that specifies the primary input pins to delete from the clock list.

- **-All**

  A switch that deletes all pins from the clock list.

Example

The following example deletes an incorrectly added clock from the clock list:

```
add_clocks 1 clock1
add_clocks 1 clock2
delete_clocks clock1
```

Related Commands

add_clocks

report_clocks

delete_config_elements

Context: all contexts including unspecified

Mode: all modes

Usage

delete_config_elements *config_objects* |
{*config_name_list* [-in_wrapper *wrapper_object_spec*]}

Description

Deletes one or more configuration elements. Only elements which can be added can be deleted.

Singular elements such as a wrapper declared with Repeatable set to single in the metadata and properties cannot be deleted as they always exist as soon as their parent wrapper exist.

Arguments

- *config_object*

  An optional collection containing one or more configuration elements. When using a collection of object, the -in_wrapper option cannot be used as the objects contains the full path of the object

- *config_name_list*

  An optional value that specifies the name of a configuration element or a Tcl list containing names of configuration elements. When the -in_wrapper option is specified, the names are relative to the specified wrapper element.

- -in_wrapper *wrapper_object_spec*

  An optional option value pair that is used to specify the parent wrapper in which the configuration elements are to be deleted. The wrapper_object_spec value is the name of a wrapper or a collection containing a wrapper element. The names in the config_name_list are relative to the specified “wrapper_object_spec”.

Example

The following example deletes elements using the full name of elements, using a relative name with respect to a parent wrapper and using a collection of objects.

```
> delete_config_elements {
    DftSpecification(mod1,rtl)/IjtagNetwork/HostScanInterface(1)
    DftSpecification(mod1,rtl)/IjtagNetwork/HostScanInterface(2) }
> delete_config_elements {HostScanInterface(1) HostScanInterface(2)} \
    -in_wrapper DftSpecification(mod1,rtl)/IjtagNetwork
> delete_config_elements [get_config_elements HostScanInterface \
                            -in DftSpecification(mod1,rtl)/IjtagNetwork
```

Related Commands

add_config_element

get_config_elements

delete_config_messages

Context: all contexts

Mode: all modes

Usage

delete_config_messages ***config_object_spec***
[-hierarchical]
[-all | [-error] [-warning] [-info]]
[-silent]

Description

Deletes error, warning or info message that were added to configuration elements using the add_config_message command.

Arguments

- ***config_object_spec***

  A required value that specifies a configuration object on which to delete the messages. The config_object_spec value is the name of a configuration element or a collection containing a single configuration element object.

- -hierarchical

  An optional Boolean option that specifies that the config message should be deleted on the specified config_object_spec and all elements below it. The -hierarchal option is ignored when the config_object_spec is a property.

- -all

  An optional Boolean option that specifies that all message types are to be deleted. The use of the -all option is mutually exclusive to the specification of the -error, -warning, and -info options. When none of the four options is specified, -all is assumed.

- -error

  An optional Boolean option that specifies that the messages to be deleted are of type error. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

- -warning

  An optional Boolean option that specifies that the messages to be deleted are of type warning. The use of the -error option is mutually exclusive to the specification of the -error, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

- -info

  An optional Boolean option that specifies that the messages to be deleted are of type info. The use of the -error option is mutually exclusive to the specification of the -all option. When none of the -error, -warning and -info options is specified, -all is assumed.

- -silent

  An optional Boolean option that disables the warning that is normally generated if the specified configuration element does not contain any messages of the specified type.

Example

The following example deletes all message on and below the wrapper DftSpecification(moda,rtl). The addition and deletion of messages on the DftSpecification and DefaultsSpecification/DftSpecification wrappers is automatically handled by the process_dft_specification command.

```
delete_config_messages DftSpecification(moda,rtl) -hierarchical
```

Related Commands

add_config_message

get_config_messages

report_config_messages

delete_config_tabs

Context: all contexts

Mode: all modes

Usage

delete_config_tabs [*config_object_spec*] [-silent]

Description

Deletes one or many configuration tree tabs from the Configuration Data window that was previously added using add_config_tab or display_specification.

When no config_object_spec value is specified then all existing tabs are deleted.

Arguments

- *config_object_spec*

  An optional value that specifies one or more configuration wrappers. The value is either the name of a wrapper, a tcl list of names of wrappers or a collection containing one or more configuration wrappers. The wrappers are the root wrapper displayed in the tab.

- -silent

  An optional value that disables the warning that is normally generated when config_object_spec contains a configuration element that is not a root wrapper displayed in an existing tab or when no configuration tab exists at all.

Example

The first example deletes the tab in which the DftSpecification(mod1.rtl) wrapper is displayed. The second example deletes all tabs and suppresses the warning that would be generated if there are no tab to delete.

```
> delete_config_tabs DftSpecification(mod1.rtl)
> delete_config_tabs -silent
```

Related Commands

add_config_tab

display_specification

delete_connections

Context: all contexts

Mode: insertion

Usage

delete_connections ***obj_spec*** [-silent]

Description

Disconnects net, pin, or port objects.

If the disconnected object is a pin, the pin is left without a connection in the instance independent of whether the pin is an input, output, or inout pin. If the object is a port, if the associated net of the same name is connected to any other object, the tool creates a uniquified net and uses it in all of the connections the original net made. This results in input and inout ports with no fanout, and output and inout ports with no fanin. If the object is a net that is also a pin, the tool creates a uniquified net and uses it in all of the connections the original net made. This results in input and inout pins with no fanout, and output and inout ports with no fanin.

You must be careful when using the delete_connection command inside a non-uniquified design. You must only do the move or disconnection once per module and once per generate loop count. See how the parent_instance and the leaf_name_hash attributes are used in section 3 of Example 5 in the get_dft_cell command description to perform this robustly.

Arguments

- ***obj_spec***

  The obj_spec must be a single net, pin or port name, a Tcl list of net, pin, or port names, or a collections of net, pin or port names created by the get_nets, get_pins, or get_ports commands.

  If an object within obj_spec does not exist and the -silent option is specified, the object is ignored. If an object within obj_spec does not exist and the -silent option is not specified, the tool generates an error.

- -silent

  An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages.

Example 1

The following example disconnects the net or constant that may be connected to input pin u1/A.

delete_connections u1/A

```
{}
```

Example 2

The following example disconnects the net or constant that may be connected to the pin within the generated collection.

delete_connections [get_pins ABC*/TE]

```
{}
```

Example 3

The following example disconnects the internal fanout of the input pin ABC/in1. It does that by renaming the net ABC/in1 to ABC/in1_ts1. The pin ABC/in1 ends up with no fanout.

delete_connections [get_nets ABC/in1]

```
{ABC/in1_ts1}
```

Example 4

The following example disconnects the internal fanin of the output port out1. It does that by renaming the net out1 to out1_ts1. The port out1 ends up with no fanin.

delete_connections out1

```
{out_ts1}
```

Related Commands

get_icl_pins
get_icl_ports
move_connections

delete_core_descriptions

Context: all contexts

Mode: setup

Usage

delete_core_descriptions {**-all** | **-cores** ***core_name_list***} [-modes *mode_name_list*]

Description

Removes core descriptions that have been read in using the read_core_descriptions command from memory.

You cannot delete a core description that is instantiated in another core description unless you specify to delete the parent core description also, by using the -all switch for example.

If a corresponding core instance exists for the core description, this command deletes the core instance along with the core description.

If you specify to delete multiple descriptions and the deletion of one or more core descriptions fails, this command will continue deletion of the remaining core descriptions.

The deletion of a top-level core description is only allowed in a non-extraction flow.

Arguments

- **-all**

  A switch that specifies to delete all core description files in the current design.

- **-cores** ***core_name_list***

  A required switch and Tcl list that specifies the core names of the core descriptions to be deleted.

- -modes *mode_name_list*

  An optional switch that specifies the mode of the core to delete.

Example

The following example reads in the core descriptions from the top_core_des file and then reports the defined core descriptions. The top-level core description is then deleted from memory. The second_level_core becomes the top of the design. The report_core_descriptions command then reports the defined core descriptions after the top-level core description is deleted.

```
set_context patterns -scan_retargeting
read_core_descriptions top_core_des
report_core_descriptions

Name                  Mode Name    Mode Type
-------------------   -----------  -----------
* top                 retargeting  retargeting
  second_level_core   retargeting  retargeting
```

```
  core1              mode_M1      internal
                     mode_M3      internal
  core2              mode_M2      internal
  core3              mode_M2      internal
                     mode_M3      internal

delete_core_descriptions -core top
set_current_design second_level_core
report_core_descriptions

Name                 Mode Name    Mode Type
-------------------  -----------  -----------
* second_level_core  retargeting  retargeting
  core1              mode_M1      internal
                     mode_M3      internal
  core2              mode_M2      internal
  core3              mode_M2      internal
                     mode_M3      internal
```

report_core_descriptions
write_core_description

delete_core_instances

Context: patterns -scan, patterns -scan_retargeting

Mode: setup

Usage

delete_core_instances {**-all** | [-cores *core_names*] | [-modules *module_objects*] | **[**-instances *instance_objects*] | [-current_design]} [-modes *mode_names*] [-silent]

Description

Removes an instance binding created with the add_core_instances command.

You can use this command to retarget patterns for different configurations sequentially in the same tool session. After completing one configuration and before switching to the next configuration, you use the delete_core_instances command to delete the old core instances so that the core instances used in the next session can be added.

Arguments

- **-all**

  A switch that specifies to remove all bindings that have been added with the add_core_instances command.

- -cores *core_names*

  An optional switch and Tcl list that specifies the core names of the core descriptions from which all instance bindings should be removed.

- -modules *module_objects*

  An optional switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. This command removes the instance bindings for each instantiation of those modules in the design.

- -instances *instance_objects*

  An optional switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. This command removes the instance bindings for each instance in the list.

- -current_design

  An optional switch that specifies to delete the core instance with respect to the current design. This switch is mutually exclusive with the -core, -modules, and -instances switches.

- -modes *mode_names*

  An optional switch and string pair that specifies the list of modes to delete for each specified core instance.

- -silent

  An optional switch that specifies to suppress warning messages.

Example 1

The following example adds the same instance twice. The second attempt fails with a warning, deletes it, and re-adds it successfully.

```
add_core_instances -instances core_1 -cores my_core
//  Added core instance 'core_1'.
add_core_instances -instances core_1 -cores my_core
//  Warning: Instance 'core_1' has already been added. Skipping.
delete_core_instances -instances core_1
add_core_instances -instances core_1 -cores my_core
//  Added core instance 'core_1'.
```

Example 2

The following example adds two instances of the same module and then deletes both of them.

```
add_core_instances -instances {core_1 core_2} -cores my_core
//  Added core instance 'core_1'.
//  Added core instance 'core_2'.
delete_core_instances -instances {core_1 core_2}
```

Example 3

The following example adds two instances and then attempts to delete the two instances as well as one other instance that has not been added. The -silent usage suppresses the warning messages that would be printed for the three non-existing core instances.

```
add_core_instances -instances {core_1 core_2} -cores my_core
delete_core_instances -instances {core_1 core_2 core_3}
//  Warning: Instance 'core_3' of module 'my_core_2' has not been added as
   a core instance. Skipping.
delete_core_instances -instances {core_1 core_2 core_3} -silent
```

Example 4

The following example adds two instances of the same module and then deletes both of them through the module.

```
add_core_instances -instances {core_1 core_2} -cores my_core
//  Added core instance 'core_1'.
//  Added core instance 'core_2'.
delete_core_instances -modules my_module
```

Related Commands

add_core_instances

delete_design

Context: all contexts

Mode: setup

Usage

delete_design

Description

Removes the current design including the flattened model, and all tool data that is design-specific.

This command also closes any open DFTVisualizer windows. Note that this command does not delete cell libraries unless a flattened model is deleted.

When the delete_design command is deleting a flat model, and that flat model was saved with a list of enabled/disabled commands, then the restriction on the disabled commands is removed. In other words, all commands allowed in the tool will be enabled for the next design.

Arguments

None

Example

The following example removes all current designs:

```
delete_design
```

Drc_pattern {{**Test_setup** [{{-Cycle | -Time} *n1*} [*n2* | End]]} | **Load_unload** | **SHIft** |
SKew_load | **SHADOW_Control** | **Master_observe** |
SHADOW_Observe | **STate_stability** | **TEST_End** [*time* | -All]}

Note

The following arguments are not supported in dft -scan: Pattern_index, Parallel_pattern, Fault_status, and Seq_depth_data.

Description

Removes a data column from the DFTVisualizer Data window.

This command has the same arguments and usage as the add_display_data command.

You can control the display of a column by right clicking on the title bar and selecting/deselecting the appropriate option.

Examples

The following example adds a column named “drc test_setup -cycle 5 10” that displays the simulated values for cycles 5 through 10 of the test_setup procedure:

```
add_display_data drc_pattern test_setup -cycle 5 10
```

The following example deletes the column added in the preceding example:

```
delete_display_data drc test_setup -cycle 5 10
```

Note

The argument string you specify when deleting a column must match exactly the column name, including spaces.

Related Commands

add_display_data

delete_display_instances

Context: all contexts

Mode: setup, analysis

Usage

delete_display_instances {***gate_id#*** | ***instance_name***}... | **-All**
[-DIsplay *window_name*]

Description

Removes the specified design instances from a DFTVisualizer display window.

Arguments

- ***gate_id#***

  A repeatable integer that specifies the identification number of a gate you want to remove from the specified display in DFTVisualizer. The value of the gate_id# argument is the unique identification number the tool automatically assigns to every gate in the design during the model flattening process.

- ***instance_name***

  A repeatable string that specifies the name of an instance you want to remove from the specified display in DFTVisualizer.

- **-All**

  A switch that removes all the instances in the specified DFTVisualizer display.

- -Display *window_name*

  An optional switch and literal that species which DFTVisualizer windows to delete instance data from. You can specify multiple windows. Literal options include:

  DEBug — A literal that specifies the Debug window.

  DESign — A literal that specifies the Design window.

  DAta — A literal that specifies the Data window.

  ALl — A literal that specifies all windows.

  The default is to delete instances from the Debug window only.

Examples

The following example first directs DFTVisualizer to display three instances in its Debug window, then removes one of the instances from the display:

```
add_display_instances 32 i_2_16 62
delete_display_instances 62
```

The next example removes the remaining gates from the Debug window, leaving the window blank:

delete_display_instances -all

report_display_instances

delete_edt_blocks

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Usage

delete_edt_blocks **-All** | ***block_name***

Description

Removes the data for the specified EDT block(s) from the tool's internal database.

The delete_edt_blocks command removes all data for the specified EDT block(s) from the tool's internal database, making the block(s) unavailable for use with the set_current_edt_block command.

If you delete the current EDT block, leaving just one remaining EDT block defined, the tool automatically sets the EDT context to the remaining block. The tool does not reset the EDT context, however, if there is more than one defined EDT block remaining; in this case subsequent context-sensitive commands that define attributes for a given EDT block will return an error until you set the EDT context using the add_edt_blocks or set_current_edt_block command.

You set or change the EDT context when you restrict the applicability of certain commands to a particular EDT block by issuing the add_edt_blocks or set_current_edt_block command. The EDT block on which context-sensitive commands currently operate is referred to as the current EDT block. The current EDT block remains the sole target of the context-sensitive commands until you delete its definition using the delete_edt_blocks command or change the context to a different EDT block using the add_edt_blocks or set_current_edt_block command. The add_scan_chains command, EDT-specific commands that define attributes for a given block, and some reporting commands are presently the only context-sensitive commands. Most commands like set_system_mode, report_statistics and create_patterns, are unaffected by the EDT context and always operate on the whole design.

Arguments

- **-All**

  A switch that specifies to remove the data for all EDT blocks from the tool's internal database.

- ***block_name***

  A string that specifies to remove the data for a particular EDT block from the tool's internal database.

Example 1

The following example displays currently defined EDT block names, then removes the definition for the one representing the current EDT block.

report_edt_blocks

```
//  my_core1_block
//  my_core3_block   (current block)
```

delete_edt_blocks my_core3_block
report_edt_blocks

```
//  Block deleted. my_core1_block is now the current EDT block.
```

Example 2

The following example shows how the tool manages the current EDT context when there are more than two blocks defined.

report_edt_blocks

```
// my_core1_block
// my_core2_block
// my_core3_block
// my_core4_block   (current block)
```

delete_edt_blocks my_core3_block
report_edt_blocks

```
// my_core1_block
// my_core2_block
// my_core4_block   (current block)
```

delete_edt_blocks my_core4_block

```
// Block deleted. No EDT block now selected as current block.
```

set_edt_options -channels 4

```
// Error: No current EDT block defined.
```

set_current_edt_block my_core2_block
set_edt_options -channels 4
report_edt_configuration

```
//
// EDT block "my_core2_block"
// --------------------------
// IP version:                     3
// External scan channels:         4
// Bypass logic:                   On
// Lockup cells:                   On
// Clocking:                       edge-sensitive
//
// Note: Only current EDT block "my_core2_block" is reported. Use "report
//    edt configuration -all_blocks" to report the configurations of all
//    blocks.
```

Related Commands

add_edt_blocks
report_edt_blocks
set_current_edt_block

delete_edt_configurations

Context: dft -edt

Mode: setup

Prerequisites: One or more compression configurations must be defined with the add_edt_configurations command.

Usage

delete_edt_configurations **-All** | ***config_name***

Description

Deletes specified compression configurations from all blocks in a design.

In a multi-block design flow, all subsequently added blocks inherit the defined compression configurations. The compression configuration parameters are then set for each block context.

Arguments

- **-All**

  A required switch that deletes all the compression configurations from all the blocks of the design.

- ***config_name***

  A required string that specifies the name of a single compression configuration to delete from all the blocks of the design.

Example

The following example reports the currently defined compression configurations in a design, deletes one, and reports the remaining compression configurations.

report_edt_configuration

```
// my_core1_block
// IP version:                    1
// Bypass logic:                  On
// Lockup cells:                  On
// Clocking:                      edge-sensitive
// Input channels:   [manufacturing_test : 10] [system_test : 4]
// Output channels:  [manufacturing_test : 5] [system_test : 2]
// Bypass chains: 5
```

delete_edt_configurations system_test
report_edt_configuration

```
// my_core1_block
// IP version:                1
// Bypass logic:              On
// Lockup cells:              On
// Clocking:                  edge-sensitive
// Input channels: [manufacturing_test : 10]
// Output channels:[manufacturing_test : 5]
```

```
// Bypass chains: 5
```

Related Commands

add_edt_configurations
report_edt_configurations
set_current_edt_configuration

delete_edt_connections

Context: dft -edt

Mode: setup

Usage

delete_edt_connections [-Signal ***type*** [-Blocks {*block_name* ...} | -All_blocks]] [{-From *connection_pathname*} {-To {*connection_pathname*...}}]

Description

Deletes connections previously specified with the add_edt_connections command.

Arguments

- -Signal ***type***

  Optional switch and literal pair that specifies an EDT control signal. Valid literals include:

  clock — specifies the edt_clock pin.

  reset — specifies the edt_reset pin.

  scan_enable — specifies the top-level scan_en pin.

  bypass — specifies the edt_bypass pin.

  update — specifies the edt_update pin.

  edt_configuration — specifies the edt_configuration pin for dual configuration applications.

  master_clock — specifies the master_clock pin. Use in latch-based EDT logic for LSSD designs only.

  slave_clock — specifies the slave_clock pin. Use in latch-based EDT logic for LSSD designs only.

  input_channel *N* — appended with the channel number to specify an EDT input channel.

  output_channel *N* — appended with the channel number to specify an EDT output channel.

- -Blocks *block_name* **...**

  Optional switch and repeatable string pair that specifies one or more blocks to target. If no blocks are specified, the current one is assumed.

- -All_blocks

  Optional switch that specifies all blocks. If no blocks are specified, the current one is assumed.

- -To *connection_name*

  Optional switch and repeatable string pair that specifies the pathname of the destination pin/node for the targeted connection.

- -From *connection_name*

  Optional switch and string pair that specifies the pin pathname of the source pin/node for the targeted connection.

Example

The following example adds block-level EDT signal connections and then deletes one and re-adds it.

Specify connections to block-level EDT signals:

```
add_edt_connections -signal input_channel 1 -to TK_channel_in[0] -block B1
add_edt_connections -signal output_channel 1 -to TK_channel_out[0] -block B1
add_edt_connections -signal input 1 -to TK_channel_in[1] -block B2
add_edt_connections -signal output 1 -to TK_channel_out[1] -block B2
add_edt_connections -signal clock -to TK_clk -blocks B1 B2
add_edt_connections -signal update -to TK_upd -all_blocks
add_edt_connections -signal bypass -to /tap_i/tap_ctrl_i/edt_bypass_inst -all_blocks
```

Delete an EDT connection:

```
delete_edt_connections -signal bypass -all_blocks
```

Re-add the EDT connection:

```
add_edt_connections -signal bypass -to /tap_i/tap_ctrl_i/edt_bypass_inst -all_blocks
```

Related Commands

add_edt_configurations

report_edt_connections

delete_false_paths

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_false_paths [-All] [-Verbose]
[-From *source_node…* | -FROM_Clock *clock_signal_name…*]
[-TO *sink_node…* | -TO_Clock *clock_signal_name…*]
[{-THrough *through_node…*}…]

Description

Removes definitions of false paths.

The delete_false_paths command deletes from the tool's internal database, false paths you defined using the add_false_paths command.

Arguments

Tip: When using the following arguments, you can include any number of asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- -All

  An optional switch that specifies to delete all previously defined false paths.

- -Verbose

  An optional switch that directs the tool to display the definition of each deleted false path as it is deleted.

- -From *source_node…*

  An optional switch and repeatable string pair that specifies the starting point of a false path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified source node does not translate to an internal gate, the tool will transcript an error message and not delete the false path definition.

- -FROM_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the starting point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with

this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not delete the false path definition.

- -TO *sink_node…*

  An optional switch and repeatable string pair that specifies the end point of a false path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified sink node does not translate to an internal gate, the tool will transcript an error message and not delete the false path definition.

Note

For two port latches with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “delete_false_paths... -to CLK2” would delete false paths that have an end point at D2.

- -TO_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the end point of a false path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

  If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not delete the false path definition.

- {-THrough *through_node…*}…

  An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the false path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

  When you use multiple -Through arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified false path. For example, the following false path specification:

  delete false paths -from A -through B C -through D E -to F

  specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the -Through argument when specifying a path, the tool will

consider all paths from the specified starting points to the specified end points to be false paths.

If a through node does not translate to an internal gate, the tool will transcript an error message and not delete the false path definition.

Example

The following example displays current false path definitions, then deletes one of them, echoing its definition as it is deleted:

report false paths -all

```
// False Path -from /my_design/a /my_design/b -through /my_design/u1
// False Path -to /my_design/c
// False Path -through /my_design/u24 /my_design/u25
// Total reported paths = 3
```

delete false paths -verbose -to /my_design/c

```
// Deleting false paths ...
// False Path -to /my_design/c ( /my_design/c/Y (36) )
// Deleted 1 false paths.
```

Refer to the add_false_paths command for examples of signal matches for pathnames specified using the asterisk (*) character.

delete_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Usage

Bridge Faults usage:
delete_fault_sites {**-All** | {***bridge_name***… **-NAME**}}

Path Delay Faults Usage:
delete_fault_sites {**-All** | **-Unsensitizable_paths** | ***path_name***…}

UDFM Faults Usage:
delete_fault_sites {**-All** | ***file_name***}

Description

Removes bridge entries, delay paths, user-defined fault sites, and any associated faults from the current fault list. For UDFMs, all faults are removed.

Depending on the current fault model, deletes specified fault sites (bridge entries or delay paths) from the current fault list. The delete_fault_sites command removes faults loaded with the read_fault_sites command. When a fault site is removed from the current fault list, the associated patterns are also removed from the internal pattern set.

For more information on bridge faults and the bridge fault definition file, refer to "The Static Bridge Fault Model" in the *Tessent Scan and ATPG User's Manual*.

For more information on path delay faults and the path definition file, refer to "Creating a Path Delay Test Set" in the *Tessent Scan and ATPG User's Manual*.

For more information on UDFMs, see "User-Defined Fault Modeling" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- **-All**

  A switch that specifies to remove all fault sites from the current fault list and deletes all faults associated with the deleted fault sites.

- ***bridge_name***

  A repeatable string that specifies a bridge name.

- **-NAME**

  A switch that specifies the argument strings preceding the switch are bridge names. This switch is required just once, whether you enter one or multiple *bridge_name* strings.

- **-Unsensitizable_paths**

  A switch that directs the tool to perform an ATPG analysis of each path, and to delete those proved unsensitizable. For a list of critical paths identified by static timing analysis, for example, use this switch to identify and delete the unsensitizable paths.

Note

This ATPG process may be very lengthy. A progress message is displayed after every 100 paths analyzed, as well as at the end of the analysis.

- ***path_name***

  A repeatable string that specifies the name of an existing path that resides in the current path definition file and whose path delay faults you want to remove from the current path delay fault list.

- **file_name**

  A required string that specifies a UDFM file name. Use this option to delete all fault sites associated with a specified UDFM file.

Example 1

The following example reads the bridge information in the bridge fault definition file, */user/design/bridgefile*, then deletes two of the three valid entries added to the fault site list:

set_fault_type bridge
read_fault_sites /user/design/bridgefile

```
//
//  Load bridge entries from file "/user/design/bridgefile".
//
//  5 bridge entries were read from file "/user/design/bridgefile".
//  2 bridge entries were skipped due to unknown net name.
//  3 bridge entries were added to the fault site list.
```

report_fault_sites

```
BRIDGE "U7.BRIDGE" {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
BRIDGE "U5.BRIDGE" {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
BRIDGE "U0.BRIDGE" {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
```

delete_fault_sites U5.BRIDGE U7.BRIDGE -name
report_fault_sites

```
BRIDGE "U0.BRIDGE" {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
}
```

Example 2

The following path delay example reads the path information from the file, */user/design/pathfile*, and deletes one of the two paths:

set_fault_type path_delay
read_fault_sites /user/design/pathfile
report_fault_sites

```
PATH “path0” =
    PIN /I$6/Q + ;
    PIN /I$35/B0 + ;
    PIN /I$35/C0 + ;
    PIN /I$1/I$650/IN + ;
    PIN /I$1/I$650/OUT - ;
    PIN /A_EQ_B + ;
END ;
PATH “path1” =
    PIN /I$6/Q + ;
    PIN /I$35/B1 + ;
    PIN /I$35/C1 + ;
    PIN /I$1/I$649/IN + ;
    PIN /I$1/I$649/OUT - ;
    PIN /I$5/D - ;
END ;
```

delete_fault_sites path0
report_fault_sites

```
PATH “path1” =
    PIN /I$6/Q + ;
    PIN /I$35/B1 + ;
    PIN /I$35/C1 + ;
    PIN /I$1/I$649/IN + ;
    PIN /I$1/I$649/OUT - ;
    PIN /I$5/D - ;
END ;
```

Example 3

The following example deletes all fault sites associated with the *c090_std.udfm* UDFM model:

delete_fault_sites /home/design/c090_std/c090_std.udfm

Example 4

The following example deletes all fault sites from the current fault list:

delete_fault_sites -All

{**-CLOCK_Domains** {**ALL** | ***clock_pathname…***} [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains]} |
{**-CAPture_procedures** {**ALL** | ***capture_procedure_name…***}}}[-Stuck_at [01 | 0 | 1]]} |
{[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYnchronous_controls]}} [-VERbose]

Bridge Faults Usage:
delete_faults {**-All** | {**-Class** {***class_name*** | ***class_code***}…}
| {{***bridge_name***… -NAME} | {***net_pathname***… -SINGle}
| {***instance_name***… -SINGle}}
| {**-CLOCK_Domains** {**ALL** | ***clock_pathname…***} [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains]}
| {**-CAPture_procedures** {**ALL** | ***capture_proc_name…***}}
| {[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYnchronous_controls]}

UDFM Fault Usage:
delete_faults { **-All** | { **-Class** { ***class_name*** | ***class_code*** } ... }
| { ***object_expression*** ... [-INstance] }
| { **-CLOCK_Domains** { **ALL** | **clock_pathname** ... } [-NO_EQUivalent_clocks]
[-INCLUDE_INTER_NORACE_clock_domains] }
| [-CLOCK_Cones]
| { [**-Udfm_type** ***name***] [**-CEll** ***name***] [**-MODule** ***name***]
[**-FAult** ***name***] } [-VERBose]

Power-Aware Options (applicable only after you have loaded CPF/UPF power data):
[[–ON_domains] | [-OFf_domains] | [-POWer_domains {*domain_name* …}]]
[-ISolation_cells] [-LEvel_shifters] [-REtention_cells]

Description

Removes faults from the current fault list.

The delete_faults command deletes from the fault list, faults you added using the add_faults or read_faults command. The power-aware options remove faults based on power domains and/or power features after you have loaded a CPF or UPF file.

Alternatively, you can also delete a large number of *non-protected faults* using the read_faults commands's -Delete switch.

When you issue this command, the tool discards all patterns in the current test pattern set. To save the current test patterns you must explicitly save them with the write_patterns command prior to issuing the delete_faults command.

By default, the delete_faults command ignores the constraint values implied in the data path when deleting faults in the data path. However, the tool still considers the constraint values for clock path faults.

You cannot use a single command to delete_faults for clock domains, capture procedures, and specific classes, objects, or paths. Use a separate command instance for each.

When bridge faults are deleted, the currently loaded faults sites remain intact.

Arguments

- **-All**

  A required switch that deletes all faults in the current fault list.

- -Keep_protected

  An optional switch, specified with the -All switch, that deletes all faults except the protected faults.

- ***name_of_delay_path***

  A required, repeatable string that specifies the name of the delay path to delete from the current fault list. The name must correspond to the name of a delay path defined in the path definition file.

- **-Protected**

  A required switch that deletes only the protected faults.

- **-Class** {***class_name*** | ***class_code***}…

  A required switch and repeatable literal pair that deletes one or more classes of faults. This argument is valid only for unprotected faults.

  Table 7-8 lists the valid fault *class_codes* and their associated fault *class_names.*

Table 7-8. Fault Class Codes and Class Names

Fault Class Codes	Fault Class Names	Fault Class Coverage
FU	Full	TE+UT
TE	TEstable	DT+PD+AU+UD
DT	DETEcted	DS+DI+DR

Table 7-8. Fault Class Codes and Class Names (cont.)

Fault Class Codes	Fault Class Names	Fault Class Coverage
DS	DET_Simulation	
DI	DET_Implication	
DR	DET_Robust (Path Delay Testing only)	
DF	DET_Functional (Path Delay Testing only)	
PD	POSDET	PT+PU
PU	POSDET_Untestable	
PT	POSDET_Testable	
AU	Atpg_untestable	
UD	UNDetected	UC+UO
UC	UNControlled	
UO	UNObserved	
UT	UNTestable	UU+TI+BL+RE
UU	UNUsed	
TI	TIed	
BL	Blocked	
RE	Redundant	

- -Both | -Rise | -Fall

  An optional switch that specifies which faults to delete for each path already added via the Add Paths command. These switches are valid only for path delay faults.

  -Both — Deletes both the slow-to-rise and slow-to-fall faults. This is the default.

  -Rise — Deletes only the slow-to-rise faults.

  -Fall — Deletes only the slow-to-fall faults.

- ***object_expression***

  A required string representing a list of instances or pins associated with the faults you want to delete from the current fault list. Note that in the case of UDFM, you can specify only instances. You can use regular expressions that include any number of asterisk (*) and question mark (?) wildcard characters.

  Instance pathnames must be ATPG library cell instances. Pin pathnames must be ATPG library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of an ATPG library model, it is ignored. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the -Pin or -Instance switch after the *object_expression*.

- -PIN

  An optional switch that uses the *object_expression* to match only pin pathnames and then, delete the associated faults.

- -INstance

  An optional switch that uses the *object_expression* to match only instances and then, delete the associated faults.

- -MODule [-PIN *module_pin_pathname* ...] (Stuck/Transition/Toggle/Iddq only)

  A switch that specifies to interpret the object_expression argument as a module pathname. All instances of the module are affected. You can use the asterisk (*) and question mark (?) wildcards for the object_expression argument, and the tool adds the fault for all matching modules or library models.

  When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given object_expression and deletes faults for every pin specified in module_pin_pathname list.

- -Untestable

  An optional switch that deletes all identified, untestable path delay faults. Untestable faults are common when using random patterns. This includes faults that the tool cannot detect due either to constraints or the use of a single capture clock.

- ***bridge_name***

  A required, repeatable string that specifies the name of a bridge. The faults associated with the specified bridge will be deleted from the current fault list.

- ***net_pathname***

  A required, repeatable string that specifies the name of a single net. The faults associated with the specified net will be deleted from the current fault list.

- ***instance_name***

  A required, repeatable string that specifies the name of an instance. The faults associated with the specified instance will be deleted from the current fault list.

- -NAME

  An optional switch that specifies all entered strings are bridge names.

- -SINGle

  Optional switch that specifies all the entered strings are either a single net or instance. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.

  If the string specifies a net, each bridge entry associated with the net is deleted.

  If the string specifies an instance that contains a non-dominant net included in a bridge entry, the associated faults are deleted.

- **-CLOCK_Domains** {**ALL** | ***clock_pathname…***}

  A required switch and literal or repeatable string pair that specifies a list of clocks and directs the tool to delete_faults that are potentially detectable using any of the specified clocks (or equivalent clocks). For a transition fault to be potentially detectable, it must be detectable when the same clock (one of the specified clocks or an equivalent) is used for launch and capture. Any other type of fault must be detectable when one of the specified clocks or equivalents is used as the capture clock. The argument choices are as follows:

  ALL — A literal that specifies all the clocks in the design.

  clock_pathname — A repeatable string that specifies a particular clock.

  Be aware that a fault potentially detectable by a clock you specify with this switch will be deleted even if it might also be detectable by an unspecified clock.

- -NO_EQUivalent_clocks

  An optional switch that prevents the -Clock_domains switch from deleting faults in equivalent clock domains.

- -INCLUDE_INTER_NORACE_clock_domains

  An optional switch used with -Clock_domains to instruct the tool to take user-defined non-race clocks into account when deleting faults in the clock domain. You can use this switch in non-setup mode and when the clock restriction is set to be domain_clock.

- **-CAPture_procedures** {**ALL** | ***capture_procedure_name…***}

  A required switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to delete_faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

  ALL — A literal that specifies all enabled named capture procedures.

  capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

  See the set_capture_procedures command description for information about enabling or disabling named capture procedures.

- -Stuck_at 01 | 1 | 0

  An optional switch and literal pair that specifies the stuck-at or transition faults to delete from the fault list.

  01 — A literal specifying that for stuck-at faults the tool delete both stuck-at-0 and stuck-at-1 faults; or for transition faults the tool delete both slow-to-rise and slow-to-fall faults. This is the default.

  0 — A literal specifying to delete only the stuck-at-0 faults (slow-to-rise faults for transition faults).

  1 — A literal specifying to delete only the stuck-at-1 faults (slow-to-fall faults for transition faults).

The following switches, which support stuck-at, transition, toggle, Iddq and bridge faults, delete faults at certain locations that are ATPG untestable in functional mode or should not be tested (to avoid over-testing). For bridge faults, the switches apply to any bridge that has at least one end in a specified location. When justified by your knowledge of the design, use the switches to fine-tune the fault population and improve the quality of the tool's coverage statistics.

- -SCAN_Enable

  An optional switch that deletes faults that only fan out to the select lines of multiplexers in the scan path. For this switch, a multiplexer is either a MUX simulation primitive or a nonprimitive type multiplexer composed of AND and OR gates. Basically, this switch deletes all faults that are in the fanin cone of local scan enable signals and are dominated by them.

- -CLOCK_Cones

  An optional switch that deletes all faults that only fan out to clock ports, Set/Reset ports or Read/Write control ports of memory elements, including RAM and ROM. This switch considers any memory elements, not just scan cells.

- -IO

  An optional switch that deletes faults that are either only controlled by PIs or only observed by POs. This switch only applies to PIs that are either not defined as a clock or defined as clock (or read/write control), but constrained to be off during capture.

- -ASYnchronous_controls

  An optional switch that deletes all faults that only fan out to Set/Reset ports of state elements and RAMs. Notice that this switch applies to a subset of the faults the -CLOCK_Cones switch deletes.

- -VERbose

  An optional switch that outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

  By default when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, the tool outputs a summary message similar to the following:

  ```
  // Note:  Adding faults for 330 fault sites.
  ```

  If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

- **-Udfm_Type *name***

  A required switch and string pair that specifies a type of UDFM fault to delete from the current fault list. The name can contain wildcards.

- **-CEll *name***

  A required switch and string pair that specifies a library cell. Use this option to delete all faults associated with a specified cell. The name can contain wildcards.

- **-MODule *name*** (UDFM only)

  A required switch and string pair that specifies a module. Use this option to delete all faults associated with a specified module. The name can contain wildcards.

- **-Class *class_type***

  A required switch and repeatable literal pair that deletes the internal fault entries that belong to the class specified by the *class_type* argument. The *class_type* argument can be either the fault class code or a fault class name. For more information on fault classes, see "Fault Classes" in the *Tessent Scan and ATPG User's Manual*.

- **-FAult *name***

  A required switch and string pair that specifies a UDFM fault name. The name can contain wildcards.

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

- -ON_domains

  An optional switch that removes faults on all power-on domains.

- -OFF_domains

  An optional switch that removes faults on all power-off domains.

- -Power_domains {*domain_name* …}

  An optional switch and repeatable string that removes faults on the specified power domains (*domain_name*).

- -Isolation_cells

  An optional switch that removes faults on all isolation cells.

- -Level_shifters

  An optional switch that removes faults on all level shifters.

- -REtention_cells

  An optional switch that removes faults on all retention cells.

Example 1

The following example deletes a stuck-at-0 fault from the current fault list after adding all the faults to the circuit, but before creating patterns:

set_system_mode analysis
add_faults -all
delete_faults i_1006/i1 -stuck_at 0
create_patterns

Example 2

The following example deletes all stuck-at-0 AU faults. Notice the reduction in AU faults in the statistics report and the corresponding increase in the reported coverages as a result of removing these faults from the calculation. (For information on the formulas used to calculate coverage, refer to "Testability Calculations" in the *Tessent Scan and ATPG User's Manual*.)

delete_flat_model

Context: all contexts

Mode: setup

Usage

delete_flat_model

Description

Deletes a flat model that was previously created either by going to system mode analysis or by using the create_flat_model command.

You typically do not need this command because any command you use that invalidates the flat model automatically deletes the flat model at the same time. The tool also automatically deletes the flat model when you enter insertion mode.

In addition, the tool deletes the flat model when you set an attribute on a design module, instance, port, or pin that has the preserve boundary option enabled. Refer to the set_attribute_options -preserve_boundary_in_flat_model option for more information.

To free up used memory, you can use this command to delete the flat model while still in setup mode if you do not need it anymore.

You cannot use this command to delete a flat model that was read in with the read_flat_model command. In this case, you must use the delete_design command to delete the flat model.

Return value

None

Related Commands

create_flat_model

read_flat_model

delete_design

set_attribute_options

delete_icl_modules

Context: all contexts

Mode: setup

Usage

delete_icl_modules {object_spec | -all} [-silent]

Description

Deletes the specified ICL modules from memory.

If any of the specified ICL modules are instantiated below the current design, the ICL elaboration tree is destroyed and you must recreate it using a new set_current_design command.

Arguments

- object_spec

  A value that specifies one or more ICL modules to delete. The value is a single ICL module name, a Tcl list of ICL module names, or a collection of ICL module objects as returned by the get_icl_modules command. When this argument is omitted, all ICL modules are deleted.

- -all

  A switch that specifies to delete all ICL modules in the system.

- -silent

  An optional argument that specifies to not generate error messages when an ICL module specified by object_spec does not exist.

Return value

None

Example

The first example deletes three ICL modules. The second example deletes all ICL modules. The third example deletes all ICL modules with a name starting with a, b or c.

```
delete_icl_modules {mychip tap tdr}
delete_icl_modules -all
delete_icl_modules [get_icl_modules {[abc].*} -regexp]
```

Related Commands

get_icl_modules

read_icl

delete_icl_ports

Context: patterns -ijtag

Mode: setup

Usage

delete_icl_ports ***port_objects*** [-silent]

Description

Undoes the effect of the add_icl_ports command on a specified list of top level ports.

Arguments

- ***port_objects***

  A required string that specifies a design port name, a tcl list of design port names or a collection of design or icl ports.

- -silent

  An optional switch that specifies to suppress the warning messages that are normally generated when the specified port names do not exist or were never the target of previous add_icl_ports commands.

Example

The following example declares then deletes ICL DataInPort D1, and ICL DataOutPorts O1 O2 and O3.

```
set_current_design top
add_icl_ports D1 -type data_in
add_icl_ports {O1 O2 O3} -type data_out
delete_icl_ports {O1 O2 O3}
```

Related Topics

add_icl_ports

delete_icl_scan_interfaces

Context: patterns -ijtag, dft

Mode: setup, insertion (dft context only)

Usage

delete_icl_scan_interfaces ***name_list* | -All**

Description

Deletes the specified scan interfaces previously added by add_icl_scan_interfaces from the new ICL top module that will be created during ICL extraction.

You must set the current design with set_current_design before using the delete_icl_scan_interfaces command.

Arguments

- ***name_list***

  A list that specifies the names of scan interfaces that ICL extraction will delete from the new top ICL module.

- -All

  A switch that specifies that all scan interfaces will be deleted from the new ICL top module.

Example

The following example will delete the ScanInterfaces named TAP and Internal from the new ICL top module during ICL extraction:

```
delete_icl_scan_interfaces {TAP Internal}
```

Related Commands

delete_iddq_exceptions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_iddq_exceptions {**-All** | ***original_string…***}

Description

Deletes exceptions to Iddq restrictions added with the add_iddq_exceptions command.

For more information on IDDQ, see "Creating an IDDQ Test Set" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- **-All** | ***original_string…***

  Deletes exceptions to Iddq restrictions. Choose from the following choices:

  -All — A required switch that specifies the deletion of all Iddq restrictions.

  original_string — A required repeatable string that identifies a site to which you previously applied Iddq exception. The *original string* is reported by the report_iddq_exceptions command and must be one of the following:

  - A string originally input to an add_iddq_exceptions command
  - A string generated automatically by the analyze_restrictions -Int_float_auto_except command.

Example

The following example removes an Iddq exception:

```
delete_iddq_exceptions /cpu/alu/U2392/
```

Related Commands

set_iddq_checks

delete_ijtag_logical_connection

Context: patterns -ijtag

Mode: setup

Usage

delete_ijtag_logical_connection [-from *source_pin_or_port_name*]
[-to *destination_pin_or_port_name*]

Description

Removes logical connections previously added to a design. You must specify either the source pin/port or the destination pin/port or both source and destination pins/ports.

You must specify the source pin/port or the destination pin/port or both with this command. If both the source and destination pins/ports are specified, the command removes the logical connection between them. If only the source pin/port is specified, then all logical connections that have that pin/port as the source will be removed. If only the destination pin/port is specified, then all logical connections that have that pin/port as the destination will be removed.

Arguments

- **-from** *source_pin_or_port_name*

  An optional switch and value pair that specifies the source pin/port for the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.

- **-to** *destination_pin_or_port_name*

  An optional switch and value pair that specifies the destination pin/port for the logical connection, which should be a top level module port or a hierarchical instance pin in the current top design module.

Example

The following example will add three logical connections in the current design, then delete one logical connection.

add_ijtag_logical_connection -from /i2/in -to /i2/out

add_ijtag_logical_connection -from /i3/in -to /i3/out

add_ijtag_logical_connection -from /i4/in -to /i4/out

report_ijtag_logical_connections

```
//  IJTAG Logical Connections:
//  From Source  To Destination
//  ===========  ==============
//  /i2/in       /i2/out
```

```
//  /i3/in       /i3/out
//  /i4/in       /i4/out
```

delete_ijtag_logical_connection -from /i4/in -to /i4/out

report_ijtag_logical_connections

```
//  IJTAG Logical Connections:
//  From Source  To Destination
//  ===========  ==============
//  /i2/in       /i2/out
//  /i3/in       /i3/out
```

Related Commands

add_ijtag_logical_connection

report_ijtag_logical_connections

delete_input_constraints

Context: all contexts

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

Usage

Context: dft -scan and dft-test_points

delete_input_constraints
[-ALl | *primary_input_pin_name…* | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs | -EQuivalent *equivalent_pin…*] [***constraint_switch***]

Context: patterns -scan

delete_input_constraints
[-ALl | *primary_input_pin_name…* | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs | -EQuivalent *equivalent_pin…*] [***constraint_switch***] [-HOld] [-NO_Z] [-SLow_pad [-CELL *model_name*]]

Context: patterns -ijtag

delete_input_constraints
[-ALl | *primary_input_pin_name…* | -BIDI_Only | -BIDI_Exclude| -EQuivalent *equivalent_pin…*] [***constraint_switch***]

Description

Removes previously applied constraints from primary input pins.

The delete_input_constraints command removes constraints you previously applied to primary input pins using the add_input_constraints command.

Arguments

- -ALl

  An optional switch that specifies to remove all previously applied input constraints except pin equivalents. This is the default. To remove pin equivalents, use the -Equivalent switch.

- *primary_input_pin_name*

  An optional, repeatable string that specifies the name of a primary input pin from which to remove the constraint.

- -BIDI_Only

  An optional switch that specifies to remove previously applied constraints only from bidirectional pins.

- -BIDI_Exclude

  An optional switch that specifies to remove previously applied constraints only from primary input pins that are *not* bidirectional.

- -SCAN_INputs

  An optional switch that specifies to remove previously applied constraints only from scan input pins.

- -EQuivalent *equivalent_pin*

  An optional switch and repeatable string that specify the name of a primary input pin from which to remove a previously defined equivalence specification.

- *constraint_switch*

  An optional switch that specifies a particular constraint to remove. The choices, from which you can specify only one, are as follows:

  -C0 — Constant 0

  -C1 — Constant 1

  -CX — Constant X (unknown)

  -CZ — Constant Z (high-impedance)

  -CR0 — Constant that returns to 0

  -CR1 — Constant that returns to 1

  -CT0 — Constant TIE0

  -CT1 — Constant TIE1

  -CTZ — Constant TIEZ

Tip: For additional information about the constraints associated with the preceding switches, refer to the same switches under the add_input_constraints command.

  -C_All — All C-type constraints

  -C_Default — All C-type constraints added using any of the following switches with the add_input_constraints command: -All, -Bidi_only, -Bidi_exclude, -Scan_inputs. This does not include C-type constraints added by specifying the primary input pin name explicitly.

  -C_Specified — C-type constraints added by specifying the primary input pin name explicitly.

- -HOld

  An optional switch that specifies to remove the “hold” restriction, if applicable, from the specified pins. See the description of the -Hold argument to the add_input_constraints command for more information.

- -NO_Z

  An optional switch that specifies to remove the “no-Z” restriction, if applicable, from the specified pins. See the description of the -No_z argument to the add_input_constraints command for more information.

- -SLow_pad

  An optional switch that specifies to remove the “slow-pad” restriction, if applicable, from the specified pins. See the description of the -Slow_pad argument to the add_input_constraints command for more information.

- -CELL *model_name*

  An optional switch and string pair that, together with the -Slow_pad switch, specifies to prefix the instance name of each instance of the ATPG library model of type *model_name* to the *primary_input_pin_name*, and look up each resulting name as the pin directly driven by the primary input.

Example

The following Tessent FastScan example deletes constraints from two primary inputs.

```
delete_input_constraints indata2 -c1
delete_input_constraints indata4 -c0
```

Related Commands

add_input_constraints
report_input_constraints

delete_instances

Context: all contexts

Mode: insertion

Usage

delete_instances ***obj_spec*** [-silent]

Description

Deletes the specified instance objects from the current design.

The ***obj_spec*** can be a single hierarchical instance name, a Tcl list of hierarchical instance names, or a collection of instances.

Arguments

- ***obj_spec***

  A required value that specifies one or more instances to delete.The value is a single hierarchical instance name, a Tcl list of hierarchical instance names, or a collection of instances.

- -silent

  An optional argument that specifies to not generate an error messages when an instance in the obj_spec list does not exist.

Example 1

The following example deletes the two specified instances in the tcl list:

```
delete_instances {u1/u2 u1/u4}
```

Example 2

The following example deletes the collection of instances returned by the get_instances command:

```
delete_instances [get_instances ABC* -hierarchical -of_module XYZ]
```

Related Commands

delete_iproc

Context: all contexts

Mode: all modes

Usage

delete_iproc **iproc_list** [-of_module *module_name*] [-silent]

Description

Deletes the specified list of iProcs attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.

All iProcs attached to the ICL module are deleted when iproc_list is not specified.

Arguments

- **iproc_list**

  A Tcl list of iProc names.

- -of_module *module_name*

  A required switch and value pair that constrains the command to delete only instances of iProcs attached to the module specified by *module_name*.

- -silent

  An optional switch that specifies to suppress error messages if the specified iProcs or module do not exist.

Return Value

None

Example

The following example deletes the test1 iProc from module mychip and then searches and deletes any remaining iProcs on mychip that begin with “p”.

```
delete_iproc test1 -of_module mychip
detete_iproc [lsearch -inline -all [get_iproc_list p*] -of_module mychip]
```

get_iproc_list
iProc
iProcsForModule

delete_layout_verification

Context: patterns -scan_diagnosis

Mode: analysis

Usage

delete_layout_verification {-List | -Design ***design_index_in_list***}

Description

Reports or deletes stored layout verification information from the current layout database.

Arguments

- **-Design *design_index_in_list***

  A required switch and integer pair that specifies the layout verification data the tool deletes. Use the -list switch to print index numbers for all stored design layout verification information.

- **-List**

  A required switch that directs the tool to list all the designs and corresponding layout rule violation information stored in the layout database. Each design is listed with its assigned Index number — the Index number is used as an argument to the -design switch. The -list switch does not delete any layout verification information, use the -design switch to delete layout verification data from the database.

Example

In the following example, the diagnosis lists the layout verification and design information stored in the open_layout database:

delete_layout_verification -list

```
//  Note: Layout verification information corresponding to the following
//        designs can be deleted from the layout database
//
//  Index    Stored Violation Count  Flat model file name
//  1.       611                     my_design.flat
//  2.       643                     other_design_version.flat
//
//   Note: The current design is my_design.flat (Index 1.)
//   Note: To delete any of the above, please use
//         delete_layout_verification -design <design index in the list>
//
```

In the following example, the diagnosis deletes the layout verification information for design index 1 (my_design.flat):

delete_layout_verification -design 1

```
//  Note: Deleting layout verification information corresponding
//        to my_design.flat.
//  Warning: Since the layout verification information for the
//           current design has been deleted, the layout will be closed.
```

Related Commands

create_layout

delete_lfsr_connections

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_lfsr_connections ***primary_pin***… | **-All**

Description

Removes connections between the specified primary pins and Linear Feedback Shift Registers (LFSRs).

The delete_lfsr_connections command deletes the connections between the LFSRs and the primary pins specified with the add_lfsr_connections command. You can use the report_lfsr_connections command to display all the current connections between LFSRs and primary pins.

Arguments

- ***primary_pin***

  A repeatable string that lists the primary pins whose connections to LFSRs you want to delete.

- **-All**

  A switch that deletes all of the connections between LFSRs and primary pins.

Example

The following example changes the definition of an LFSR connection by deleting it and then re-adding it with a new definition:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsr_taps lfsr1 2 3 4
add_lfsr_connections scan_in.1 lfsr1 2
delete_lfsr_connections scan_in.1
add_lfsr_connections scan_in.2 lfsr1 2
```

Related Commands

add_lfsr_connections

report_lfsr_connections

delete_lfsr_taps

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_lfsr_taps ***lfsr_name*** {***tap_position***… | **-All**}

Description

Removes the tap positions from a Linear Feedback Shift Register (LFSR).

The delete_lfsr_taps command deletes the specified LFSR tap positions added with the add_lfsr_taps command. To display the current tap positions of all defined LFSRs, use the report_lfsrs command.

Arguments

- ***lfsr_name***

  A string that specifies the reference name of the LFSR whose tap positions you want to delete.

- ***tap_position***

  A repeatable string that specifies the list of tap positions that you want to delete from the *lfsr_name*.

- **-All**

  A switch that deletes all of the tap positions from the *lfsr_name*.

Example

The following example changes an LFSR tap position by deleting it and then adding a new tap position:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsrs lfsr2 Prpg 5 13 -serial -in
add_lfsr_taps lfsr1 2 3 4
add_lfsr_taps lfsr2 1 3
delete_lfsr_taps lfsr1 3
add_lfsr_taps lfsr1 1
```

Related Commands

add_lfsr_taps
set_lfsrs
report_lfsrs

delete_lfsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_lfsrs ***lfsr_name***… | **-All**

Description

Removes the specified Linear Feedback Shift Registers (LFSRs).

The delete_lfsrs command deletes LFSRs defined with the add_lfsrs command. You can use the report_lfsrs command to display a list of the current LFSRs with their current values and tap positions. When you delete an LFSR, the tool also deletes all its taps and pin connections.

Arguments

- ***lfsr_name***

  A repeatable string that specifies the reference names of the LFSRs that you want to remove.

- **-All**

  A switch that deletes all defined LFSRs.

Example

The following example changes the definition of an LFSR by deleting it and then re-adding it with a new definition:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsrs lfsr2 prpg 5 13 -serial -in
add_lfsrs lfsr3 prpg 5 11 -parallel -out
delete_lfsrs lfsr3
add_lfsrs lfsr3 prpg 5 11 -parallel -in
```

Related Commands

add_lfsrs
set_lfsrs
report_lfsrs

delete_lists

Context: dft -edt, patterns -scan

Mode: analysis

Usage

delete_lists ***pin_pathname***... | **-All**

Description

Removes pins from the pin list the tool monitors and reports on during simulation.

The delete_lists command removes from the monitored pin list, pins that you previously added to the list using the add_lists command. To review the current list of pins, use the report_lists command. To put additional pins on the list, use the add_lists command.

Arguments

- ***pin_pathname***

  A repeatable string that specifies the pins you want to remove from the monitored pin list.

- **-All**

  A switch that removes all currently listed pins from the monitored pin list.

Example

The following example removes an extra added output pin from the monitored pin list:

add_lists /i_1006/o /i_1007/o /i_1008/o
report_lists

```
3 pins are currently monitored.
/i_1006/o
/i_1007/o
/i_1008/o
```

delete_lists /i_1007/o
report_lists

```
2 pins are currently monitored.
/i_1006/o
/i_1008/o
```

Related Commands

add_lists
report_lists

delete_misrs

Context: pattern -scan

Mode: setup, analysis

Usage

delete_misrs {**-all** | ***misr_name***}

Description

Deletes MISRs you specify with the add_misrs command.

This command is used with the hybrid TK/LBIST flow—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- **-all**

  A required switch that specifies removing all MISRs.

- ***misr_name***

  A required repeatable string that specifies the name of the MISR.

Example

This example deletes a previously added MISR called misr_0, and then re-adds the MISR as blk1_misr.

add_misrs misr_0 -size 24 -seed 000000 -taps 21 22 24

delete_misrs misr_0

add_misrs blk1_misr -size 24 -seed 0000 -taps 21 22 24

report_misrs -all

```
list of MISRs
blk1_misr  MISR  length=24  in_stream_taps=20,21,23
blk1_misr_pre_unload_value = 000000000000000000000000
```

Related Commands

add_misrs

report_misrs

delete_multicycle_paths

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

delete_multicycle_paths [-All] [-Verbose]
[-From *source_node…* | -FROM_Clock *clock_signal_name…*]
[-TO *sink_node…* | -TO_Clock *clock_signal_name…*]
[{-THrough *through_node…*}…]

Description

Removes definitions of multicycle paths previously read in using the read_sdc command.

The delete_multicycle_paths command deletes from the tool's internal database, multicycle path definitions previously read in by the read_sdc command.

Arguments

Tip: When using the following arguments, you can include asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- -All

  An optional switch that specifies to delete all multicycle path definitions.

- -Verbose

  An optional switch that directs the tool to display the definition of each deleted multicycle path as it is deleted.

- -From *source_node…*

  An optional switch and repeatable string pair that specifies the starting point of a multicycle path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the output pins of the instance to be starting points. For a clock PI, the tool considers the outputs of all the non-transparent latches, flip-flops and RAMs associated with the clock PI to be starting points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified source node does not translate to an internal gate, the tool will transcript an error message and not delete the multicycle path definition.

- -FROM_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the starting point of a multicycle path by its associated clock pin pathname. The tool interprets any pin pathname you specify

with this argument to be the source of a clock signal and considers the outputs of all non-transparent latches, flip-flops and RAMs associated with this clock signal to be starting points.

If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not delete the multicycle path definition.

- -TO *sink_node…*

  An optional switch and repeatable string pair that specifies the end point of a multicycle path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, the tool considers all the input pins of the instance to be end points. For a clock PI, the tool considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with the clock PI to be end points. The tool considers a pin pathname to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and handles the internal clock pin the same as a clock PI.

  If a specified sink node does not translate to an internal gate, the tool will transcript an error message and not delete the multicycle path definition.

Note

For two port latches with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “delete_multicycle_paths... -to CLK2” would delete_multicycle_paths that have an end point at D2.

- -TO_Clock *clock_signal_name…*

  An optional switch and repeatable string pair that specifies the end point of a multicycle path by its associated clock pin pathname. The tool interprets any pin pathname you specify with this argument to be the source of an internal clock signal and considers the data inputs of all non-transparent latches, flip-flops and RAMs associated with this clock to be end points.

  If a specified clock signal name does not translate to an internal gate, the tool will transcript an error message and not delete the multicycle path definition.

- {-THrough *through_node…*}…

  An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the multicycle path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and the tool makes no attempt to determine if a pin pathname is that of an internal clock pin.

  When you use multiple -Through arguments, the tool considers their order left-to-right in the command string to be the order in which a signal would pass through the nodes on the specified multicycle path. For example, the following multicycle path specification:

  delete multicycle paths -from G -through H I -through J K -to L

  specifies all paths that start from G, pass through either H or I, then pass through J or K, and end at L. If you do not use the -Through argument when specifying a path, the tool will

consider all paths from the specified starting points to the specified end points to be false paths.

If a specified through node does not translate to an internal gate, the tool will transcript an error message and not delete the multicycle path definition.

Example

The following example displays current multicycle path definitions, then deletes one of them, echoing its definition as it is deleted:

report multicycle paths -all

```
// Multicycle Path -from /my_design/a -through /my_design/u1 -cycles 2
// Multicycle Path -to /my_design/c -cycles 3
// Multicycle Path -through /my_design/u24 /my_design/u25 -cycles 2
// Total reported multicycle paths = 3
```

delete multicycle paths -verbose -to /my_design/c

```
// Multicycle Path -to /my_design/c (/my_design/c/Y (130)) -cycles 2
// Deleted 1 multicycle path.
```

Refer to the add_false_paths command for examples of signal matches for pathnames specified using the asterisk (*) wildcard character.

report_multicycle_paths

delete_nets

Context: all contexts

Mode: insertion

Usage

delete_nets ***obj_spec*** [-silent]

Description

Removes net objects inside an instance of a design module.

You cannot delete a net that has a fanin or fanout. You can delete only dangling nets.

You cannot delete a net that is also a pin of an instance. You can delete the corresponding input pin using the delete_pins command, but the net will remain if it has objects in its fanout. You can delete the corresponding output pin using the delete_pins command, but the net will remain if it has objects in its fanin.

In general, you cannot delete a net that is driven by any RTL construct; however, an exception is that you can delete a dangling net driven by a Verilog assign statement. When you delete such a net, you also delete the assign statement.

Arguments

- ***obj_spec***

  A required value that specifies the name of a net, a Tcl list of net names or a collection of net objects as returned by the get_nets command. If the specified net object is part of a bus net, the entire bus is deleted.

- -silent

  An optional argument that specifies to ignore specified objects that do not exist and to not generate error messages.

Example 1

The following example creates a connection between two pins using a specific net name. Once created, the net cannot be deleted until it is no longer used in any connection.

create_connections INSTA/I1 INSTB/O1 -net_name mynet
get_nets mynet

```
{mynet}
```

delete_net mynet

```
// Error: Cannot remove net 'mynet' in scope 'mychip' as it is being used
// in expression(s).
// Error: Error on 'delete_nets' at 'mynet'.
```

delete_connections { INSTA/I1 INSTB/O1}
delete_net mynet
get_nets mynet -silent

```
{}
```

Example 2

The following example checks for nets inside instance u1 with no fanin, disconnects their fanout and deletes them.

```
foreach_in_collection net [get_nets u1/*] {
   if {[sizeof_collection [get_fanins $net]] == 0} {
        delect_connections [get_fanouts $net -stop_on pin]
        delete_nets $net
   }
}
```

delete_nofaults

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_nofaults {**-All** | ***modulename*** ... **-Module** [-PIN *module_pin_pathname* ...] | ***object_expression*** ... [-PIN | -Instance]} [-Stuck_at {01 | 0 | 1}] [-Class {System | User | Full}] [-VERBose] [(> | >>) *file_pathname*]

Description

Removes the nofault settings from either the specified pin or instance/module pathnames.

The delete_nofaults command deletes nofault settings you added using the add_nofaults command.

You can optionally specify nofault settings that have a specific stuck-at or transition value. For the latter, you specify 0 for “slow-to-rise” and 1 for “slow-to-fall” transition faults. If you do not specify a stuck-at (transition) value when deleting a nofault setting, the command deletes both stuck-at (transition) nofault settings.

You can use the report_nofaults command to display all the current nofault settings.

You can also optionally specify nofault settings that have a specific class code: user-defined, system netlist, or both. If you do not specify a class code, then the command deletes the nofault setting from the user class.

Arguments

- **-All**

  A switch that deletes all nofault settings.

- ***modulename***

  A repeatable string that specifies the name(s) of the module(s) from which you want to delete nofault settings. You must include the -Module switch when you specify a module name.

- **-Module**

  A switch that specifies interpretation of the *modulename* argument as a module pathname. All instances of these modules are affected. You can use the asterisk (*) and question mark (?) wildcards for the ***modulename*** argument, and the tool deletes the nofault for all matching modules or library models.

  When you follow the -Module switch with the optional -PIN switch, you can specify a list of module pin pathnames for the pin within the module. The tool automatically finds all the instances with the given module name and deletes nofaults for every pin specified in module_pin_pathname list.

- ***object_expression***

  A string representing a list of pathnames of instances or pins from which you want to delete nofault settings. You can use regular expressions, which may include any number of asterisk (*) and question mark (?) wildcard characters.

  Pin pathnames must be ATPG library cell instance pins, also referred to as design level pins. If the object expression specifies a pin within an instance of an ATPG library model, the tool ignores it. By default, pin pathnames are matched first. If a pin pathname match is not found, the tool next tries to match instance pathnames. You can force the tool to match only pin pathnames or only instance pathnames by including the -Pin or -Instance switch after the *object_expression*.

- -Pin

  An optional switch that specifies to use the preceding object expression to match only pin pathnames; the tool will then delete nofault settings from all the pins matched.

- -Instance

  An optional switch that specifies to use the preceding object expression to match only instance pathnames; the tool will then delete nofault settings from all boundary and internal pins of the instances matched.

- -Stuck_at 01 | 0 | 1

  An optional switch and literal pair that specifies the stuck-at or transition values from which you want to remove a nofault setting. The choices are as follows:

  01 — A literal specifying that for stuck-at faults the tool delete both “stuck-at-0” and “stuck-at-1” nofault settings; or for transition faults the tool delete both “slow-to-rise” and “slow-to-fall” nofault settings. This is the default.

  0 — A literal that deletes only the “stuck-at-0” nofault settings (“slow-to-rise” nofault settings for transition faults).

  1 — A literal that deletes only the “stuck-at-1” nofault settings (“slow-to-fall” nofault settings for transition faults).

- -Class User | System | Full

  An optional switch and literal pair that specifies the source (or class) of the nofault settings which you want to delete. The valid literals are as follows:

  User — A literal that deletes the user-entered nofault settings. This is the default.

  System — A literal that deletes netlist-based nofault settings.

  Full — A literal that deletes all the nofault settings in the user and system classes.

- -VERbose

  By default when you specify wildcard characters for instance (-INstance) or pin (-PIN) names, the tool outputs a summary message similar to the following:

  // Note: Adding faults for 330 fault sites.

When you specify the optional -VERbose switch, then the tool outputs the instance or pin names instead of the summary. You can optionally redirect this output to a file using the > or >> redirection operators.

If you use actual instance or pin names instead of wildcards, then this switch has no effect.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example

The following example deletes nofault settings from the pins of instance i_1007 and then adds all faults to the circuit, thereby allowing the tool to add_faults to the pins of the i_1007 instance:

```
add_nofaults i_1006 i_1007 i_1008 -instance
delete_nofaults i_1007 -instance
set_system_mode analysis
add_faults -all
```

Related Commands

report_nofaults

delete_nonscan_instances

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_nonscan_instances {{***pathname***… | ***instance_expression*** [-INStance | -Module]} | **-All**} [-Class {User | System | Full}]

Description

Removes the specified sequential instances from the non-scan instance list.

The delete_nonscan_instances command deletes sequential instances or all instances within the specified module that were previously added to the non-scan instance list by using either the add_nonscan_instances command or the Dont_touch property in a Genie netlist. You can delete either a specific list of instance names or all instances.

To display the current non-scan instance list, use the report_seq_transparent_procedures command.

Arguments

- ***pathname***

  A repeatable string that specifies either the pathnames of the instances that you want the tool to delete from the non-scan instance list.

- ***instance_expression***

  A string representing a list of instances within the design. The string instance_expression is defined as:

  { string | string * } ...

  The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. You can use a pathname expression to select several instances and the tool will then delete_nonscan_instances for all the pins on those instances; but if the expression specifies a location below the instance level of an ATPG library model, the tool will issue an error message.

- -INStance | -Module

  A switch that specifies whether the pathnames are instances or modules. An example Verilog module is “module clkgen (clk, clk_out, …)” where clkgen is the module name. The default is -Instance.

- **-All**

  A switch that specifies to delete all instances from the non-scan instance list.

- -Class User | System | Full

  An optional switch and literal pair that specifies the source (or class) of the non-scan instance that you want to delete. The valid literals are as follows:

  User — A literal that specifies to only delete the non-scan instances entered by the user using the add_nonscan_instances command. This is the default.

  System — A literal that specifies to only delete the non-scan instances described in the Genie netlist with the Dont_touch property.

  Full — A literal that specifies to delete all the non-scan instances in the user and system class.

Examples

The following example deletes an extra sequential non-scan instance called i_1007.

```
add_nonscan_instances i_1006 i_1007 i_1008
delete_nonscan_instances i_1007
insert_test_logic
```

Related Commands

add_nonscan_instances
report_seq_transparent_procedures

delete_nonscan_models

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_nonscan_models ***model_name***… | **-All** [-Class {User | System | Full}]

Description

Removes from the non-scan model list the specified sequential DFT library models.

When you issue the add_nonscan_models command on a DFT library model, the tool places all instances of that DFT library model into the user-specified, non-scan instance list. Once you remove a model from the non-scan model list with the delete_nonscan_models command, the tool then has the freedom to decide whether to place those instances of that model in the scan instance list.

The tool decides whether to place individual instances in the scan instance list based on many parameters including the scan setup settings. For example, if the scan setup has been changed to All with the command, then the tool is forced to place all available sequential instances into the scan instance list.

Arguments

- ***model_name***

  A repeatable string that specifies the model names that you want to delete from the non-scan model list. Enter the model names as they appear in the DFT library.

- **-All**

  A switch that specifies to delete all models from the non-scan model list.

- -Class User | System | Full

  An optional switch and literal pair that specifies the class code of the non-scan model that you specify. The valid literal names are as follows:

  User — A literal that specifies that the list of non-scan models were previously added by using the add_nonscan_models command. This is the default class.

  System — A literal that specifies that the list of non-scan models were added by the tool.

  Full — A literal that specifies that the list of non-scan models consist of both the user and system class.

Examples

The following example deletes an extra sequential non-scan model called d_flip_flop2:

```
add_nonscan_models d_flip_flop1 d_flip_flop2
delete_nonscan_models d_flip_flop2
insert_test_logic
```

Related Commands

add_nonscan_instances
add_nonscan_models

delete_norace_clocks

Context: dft -edt, patterns -scan

Mode: analysis

Usage

delete_norace_clocks **-All** | ***clock_pin_name…*** | ***gate_id#…***

Description

Removes clocks from user-defined non-interacting clock domains.

The delete_norace_clocks command removes clocks from any user-defined non-interacting clock domains to which they belong. These clock domains are created originally with the add_norace_clocks command.

Arguments

- **-All**

  A switch that specifies all user-defined, non-interacting clocks previously defined with the add_norace_clocks command.

- ***clock_pin_name…***

  A repeatable string that specifies the name of a clock pin for a user-defined, non-interacting clock previously defined with the add_norace_clocks command.

- ***gate_id#…***

  A repeatable positive integer that specifies the gate identification number of a clock pin for a user-defined, non-interacting clock previously defined with the add_norace_clocks command.

Example

The following example first displays the clock domains as determined by the tool, and then displays the current user-defined non-interacting clocks and their domains. The example then removes clk4 and clk1 from their user-defined domains, and again reports the tool-defined clock domains. You can see that the user-defined clock domains do not alter the clock domains the tool determines with its own analysis.

set_system_mode analysis
report_clock_domains

```
// Clock name   Domain
// --------------------
// /clk1 (2)         1
// /clk2 (10)        2
// /clk3 (18)        3
// /clk4 (44)        4
// /clk5 (51)        5
```

report_norace_clocks

```
// User clock domain 1 : /clk1 /clk2
// User clock domain 2 : /clk3 /clk4 /clk5
```

delete_norace_clocks clk4
report_norace_clocks

```
// User clock domain 1 : /clk1 /clk2
// User clock domain 2 : /clk3 /clk5
```

delete_norace_clocks clk1
report_norace_clocks

```
// User clock domain 1 : /clk3 /clk5
```

report_clock_domains

```
// Clock name   Domain
// --------------------
// /clk1 (2)         1
// /clk2 (10)        2
// /clk3 (18)        3
// /clk4 (44)        4
// /clk5 (51)        5
```

Related Commands

add_clocks
add_norace_clocks
report_clocks
report_norace_clocks

delete_notest_points

Context: dft -scan, dft -test_points

Mode: setup, analysis

Prerequisites: You must add circuit points with the add_notest_points command before you can delete them.

Usage

delete_notest_points {***pin_pathname***… | ***instance_pathname…*** | ***instance_expression*** } | **-ALL** | {**-Path** ***critical_pathname***} | **-ALL_Paths**

Description

Removes the circuit point which the tool cannot use for testability insertion from the specified pins.

The delete_notest_points command deletes circuit points added using the add_notest_points command. These notest circuit points identify output pins of cells that the tool is not to use for insertion of controllability and observability. You can display a list of the current circuit points and their associated pins by using the report_notest_points command.

Arguments

- ***pin_pathname***

  A repeatable string that specifies a list of pins for which you want to delete the circuit points that the tool cannot use for testability insertion.

- **-All**

  A switch that deletes all previously-added circuit points.

- ***instance_pathname***

  A required repeatable string that lists the instances whose output pins you want to delete the circuit points that the tool cannot use for testability insertion. All output pins within that (hierarchical) instance are removed from the list of pins that should be excluded from consideration.

- ***instance_expression***

  A string representing a list of instances within the design. The string *instance_expression* is defined as:

  { string | string * } ...

  The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. You can use a pathname expression to select several instances and the tool will then delete_notest_points for all the pins on those instances; but if the expression

specifies a location below the instance level of an ATPG library model, the tool will issue an error message.

- **-Path *critical_pathname***

  A required switch and name pair that specifies to delete the named critical path. You can list the names of the critical paths using the report_notest_points command with the -Paths switch. For more information on the format of the file, refer to "The Path Definition File" in the *Tessent Scan and ATPG User's Manual*.

- **-ALL_Paths**

  A required switch that specifies to delete all critical paths.

Example

The following example deletes an incorrect notest circuit point and corrects it with a new circuit point before performing testability analysis:

```
set_system_mode analysis
add_notest_points tr_i ts_i
delete_notest_points tr_i
add_notest_points tr_io
```

Related Commands

add_output_masks

report_notest_points

delete_output_masks

Context: dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

delete_output_masks ***primary_output***... | **-All**

Description

Removes the masking of the specified primary output pins.

The tools use primary output pins as the observe points during the fault detection process. When you mask a primary output pin with the add_output_masks command, the tools mark that pin as an invalid primary output during the fault detection process.

You can set a default mask for all output and bidirectional pins using the set_output_masks command. You can add a hold value to a default mask with the add_output_masks command, or remove a hold value using the delete_output_masks command. To turn off the default masks for all output pins, you must use the "set_output_masks Off" command.

Arguments

- ***primary_output***

  A repeatable string that specifies the names of the primary output pins that you want to unmask.

- **-All**

  A switch that unmasks all primary outputs masked using the add_output_masks command.

Example

The following example first incorrectly chooses two of the design's primary output pins to mask. The example then unmasks the one primary output that was inappropriate, masks the correct primary output, and then displays the complete list of currently-masked primary output pins no longer available as observation points:

```
add_output_masks q1 qb3
delete_output_masks q1
add_output_masks qb1
report_output_masks
```

```
qb1
qb3
```

delete_patterns

Context: dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis, patterns -ijtag

Mode: analysis

Usage

For patterns -scan

delete_patterns [-external | -internal] [-pattern_sets [chain] [scan]] [-keep_fault_status] [-force]

For patterns -ijtag

delete_patterns [-pattern_sets *pattern_set_list*] [-force]

For patterns -scan_retargeting

delete_patterns **core_name *name*** [-mode *name*] [-silent]

Description

Deletes the current pattern set.

This command removes either the internal or external pattern set or both from the current session.

You can only delete generated pattern sets (that is, patterns generated by the tool and not read in) that have been written out using the write_patterns command, unless you use the -force switch. This restriction prevents you from deleting patterns that you have generated but have not yet written out to disk. In the -ijtag context, you can delete only patterns that have been closed.

Arguments

- -external | -internal **(patterns -scan context only)**

  Optional switches that specify which pattern source to remove. By default, the command removes both internal and external pattern sets.

- -pattern_sets [chain] [scan] **(patterns -scan only)**

  An optional switch and keyword pair that specifies which pattern type (scan or chain) to remove from the current session. By default, the tool removes both scan and chain patterns.

- -pattern_sets *pattern_set_list* **(-ijtag and patterns -scan_retargeting context only)**

  An optional switch and string that specifies a Tcl list of pattern set names that were created using the open_pattern_set command. When you don't use this switch, the command deletes all pattern sets.

- -keep_fault_status **(-scan context only)**

  Optional switch that keeps the current fault status when removing the internal patterns. When deleting the internal patterns, the status of existing faults is reset by default if you don't use this switch.

- -force

  An optional switch that forces removing the internal patterns even when they are not stored previously. By default, the tool does not allow you to remove the unsaved internal patterns. However, the -force option allows you to delete the unsaved internal patterns without this safeguard. You can always remove the external patterns.

- core_name name **(patterns -scan_retargeting only)**

  A required switch that specifies the cores from which pattern sets are to be deleted. If the core *name* does not exist, the patterns for all cores are deleted in the pattern retargetable phase.

- -mode name **(patterns -scan_retargeting only)**

  An optional switch that specifies which modes of the core the patterns should be deleted from. If -mode is not specified, all modes of the core are deleted.

- -silent **(patterns -scan_retargeting only)**

  An optional switch that specifies not to report patterns as they are deleted. By default, deleted patterns are reported.

Example 1

The following example removes all pattern sets currently in memory:

```
delete_patterns
```

Example 2 (-scan context)

The following example removes only the chain patterns from the internal pattern set. The -force option suppresses the error that would otherwise occur if you had not already saved the internal patterns using the write_patterns command.

```
delete_patterns -internal -pattern_sets chain -force
```

Example 3 (-ijtag context)

The following example removes only the patterns in the Tcl list named "pattern_list5":

```
delete_patterns -pattern_sets patterns_list5
```

Related Commands

read_patterns
simulate_patterns
write_patterns
open_pattern_set

delete_pins

Context: all contexts

Mode: insertion

Usage

delete_pins ***obj_spec*** -silent

Description

Removes pin objects from a design module instance.

If the pin to be deleted has an internal connection, the internal nets associated to the pin are kept; otherwise they are removed too.

Note

You should be aware that deleting one bit of a bus deletes the entire bus.

Arguments

- ***obj_spec***

  A required value that specifies a pin name, a Tcl list of pin names, or a collection of pin objects as returned by the get_pins command. If the specified pin object is part of a bus net, the entire bus is deleted.

- -silent

  An optional argument that specifies to not generate an error message if an object within the specified ***obj_spec*** does not exist.

Example 1

The following example deletes the specified pins names. On instance u1, pin A is a scalar port, pin B is a bus pin with indices [3:0], and port C is also a bus port with indices [7:0]. All three pins are completely deleted even though the complete bus range was not specified for pins B and C.

get_pins {u1/A u1/B u1/C}

```
{u1/A u1/B[3] u1/B[2] u1/B[1] u1/B[0] u1/C[7] u1/C[6] u1/C[5]
u1/C[4]u1/C[3] u1/C[2] u1/C[1] u1/C[0]}
```

delete_pins {u1/A u1/B u1/C[1]}
get_pins {u1/A u1/B u1/C}

```
//  Warning: No result. Please check your filtering options.
{}
```

Example 2

The following example deletes the collection of pin objects returned by the get_pins command.

delete_pins [get_pins {u1/A u1/B u1/C[1]} -silent]

Related Commands

create_pin
get_icl_pins
get_icl_ports
get_nets

delete_ports

Context: all contexts

Mode: insertion

Usage

delete_ports ***obj_spec1*** [-on_module *obj_spec2*] [-silent]

Description

Removes port objects from a design module.

If the port to be deleted has an internal connection, the internal nets associated to the port are kept; otherwise they are removed too.

If obj_spec1 is a collection of ports, those names refers to ports on specific modules and the specified -on_module option is ignored.

Note

Deleting one bit of a bus port deletes the entire bus port.

Arguments

- ***obj_spec1***

  A required value that specifies a single port name, a Tcl list of port names or a collection of port objects.

- -on_module *obj_spec2*

  An optional switch and value pair that specifies the module from which the ports are to be deleted. The obj_spec2 value can be the name of a module or a module object returned by the command. If the -on_module switch is not specified, this command deletes the port from the current design which is the module specified by the set_current_design command. You cannot delete a port on a module that was read in from a file and that is not instantiated inside the current design. It is possible to delete ports on modules created with the create_module command.

- -silent

  An optional argument that specifies to not generate an error message if an object within the specified obj_spec1 or obj_spec2 does not exist.

Example 1

The following example deletes the specified port names of module ModA. On ModA, port A is a scalar port, port B is a bus port with indices [3:0], and port C is also a bus port with indices [7:0]. All three ports are completely deleted even if the complete bus range was not specified for port B and C.

```
delete_ports {A B C[1]} -on_module ModA
```

Example 2

The following example deletes the collection of port objects returned by the get_ports command. Notice that the -on_module option is not specified for the delete_ports command because the port objects returned by the get_ports command are already associated to a specific module.

```
delete_ports [get_ports {A B C[1]} -of_module ModA]
```

Related Commands

delete_primary_inputs

Context: all contexts

Mode: setup

Usage

delete_primary_inputs {***net_pathname***... | ***primary_input_pin***... | **-All**}
[-Class {User | System | Full}]

Description

Removes the specified primary inputs from the existing flattened model or, if a flattened model does not yet exist, from the flattened result.

The delete_primary_inputs command deletes from a circuit the primary inputs that you specify. You can delete either the user class, system class, or full classes of primary inputs. If you do not specify a class, the tool deletes the primary inputs from the user class.

You can display a list of any class of primary inputs by using the report_primary_inputs command.

Note

Once you delete a primary input pin with this command, adding the pin back again with the add_primary_inputs command will not create the same pin. Bus information is lost and the pin will be marked as user-added. Take care to use delete_primary_inputs only if you wish to truly delete a pin from the design so it is not used.

Arguments

- ***net_pathname***

  A repeatable string that specifies the circuit connections that you want to delete. You can specify the class of primary inputs to delete with the -Class switch.

- ***primary_input_pin***...

  A repeatable string that specifies a list of primary input pins that you want to delete. You can specify the class of primary inputs to delete with the -Class switch.

- **-All**

  A switch that deletes all primary inputs. You can specify the class of primary inputs to delete with the -Class switch.

- -Class User | System | Full

  An optional switch and literal pair that specifies the class code of the designated primary input pins. The valid class code literal names are as follows:

  User — A literal specifying that you added the primary inputs using the add_primary_inputs command. This is the default class.

  System — A literal specifying that the primary inputs derive from the netlist.

Full — A literal specifying that the primary inputs consist of both user and system classes.

Example

The following example deletes an extra added primary input from the user class of primary inputs:

```
add_primary_inputs indata2 indata4 indata6
delete_primary_inputs indata4 -class user
```

Related Commands

add_primary_inputs

report_primary_outputs

delete_primary_outputs

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

delete_primary_outputs {***net_pathname***... | ***primary_output_pin***... | **-All**} [-Class {User | System | Full}]

Description

Removes the specified primary outputs from the existing flattened model or, if a flattened model does not yet exist, from the flattened result.

The delete_primary_outputs command deletes from a circuit the primary outputs that you specify. You can delete either the user class, system class, or full classes of primary outputs. If you do not specify a class, the tool deletes the primary outputs from the user class.

You can display a list of any class of primary outputs by using the report_primary_outputs command.

Note

Once you delete a primary output pin with this command, adding the pin back again with the add_primary_outputs command will not create the same pin. Bus information is lost and the pin will be marked as user-added. Take care to use delete_primary_outputs only if you wish to truly delete a pin from the design so it is not used.

Arguments

- ***net_pathname***

  A repeatable string that specifies the circuit connections that you want to delete. You can specify the class of primary outputs to delete with the -Class switch.

- ***primary_output_pin***

  A repeatable string that specifies a list of primary output pins that you want to delete. You can specify the class of primary outputs to delete with the -Class switch.

- **-All**

  A switch that deletes all primary outputs. You can specify the class of primary outputs to delete with the -Class switch.

- -Class User | System | Full

  An optional switch and literal pair that specifies the class code of the primary output pins that you specify. The valid literal names are as follows:

  User — A literal specifying that the list of primary outputs were added using the add_primary_outputs command. This is the default class.

System — A literal specifying that the list of primary outputs derive from the netlist.

Full — A literal specifying that the list of primary outputs consists of both the user and system class.

Example

The following example deletes a primary output from the system class of primary outputs:

```
delete_primary_outputs outdata1 -class system
```

Related Commands

add_primary_outputs

report_primary_outputs

delete_processors

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion (dft -edt context only)

Usage

delete_processors [*hostname*[:*cpus*]]…

Description

Removes processor definitions previously specified with the add_processors command.

The delete_processors command deletes slave processor definitions you previously specified using the add_processors command. When you issue the command with no arguments, the tool discontinues all current slave processes. If you specify one or more *hostname* arguments, the tool will discontinue slave processes only on the specified host machines. If you include :*cpus* with *hostname*, the tool will discontinue only the specified number of slave processes on that host machine. Without the :*cpus*, all current slave processes on that host machine are discontinued. When specifying *hostname*, you must specify the network name of the machine, even if it was originally selected by an LSF, SGE, or custom job scheduler.

Be aware that the process run by an LSF, SGE, or custom job scheduler is a script rather than the actual slave process. If you discontinue these slave processes with the delete_processors command, the corresponding scripts also terminate.

Tip: Alternatively, you can end execution of the scripts by using the job scheduler commands (SGE's **qdel**, LSF's **bkill**, or whatever is used by the job scheduler invoked by the add_processors Generic command) or a Linux **kill** command. There will be a small delay before the slave process is actually shut down to allow for the detection of the script death and for the shutdown to be coordinated with the master process. Slave processes shut down in this manner will appear to have died in the master process's transcript. This is normal behavior. Detection of script deaths occurs only during the add_processors, delete_processors, and report_processors commands. You can force detection from the command line without other side effects by issuing the report_processors command with no arguments.

Arguments

- *hostname*

  A repeatable string that specifies a host machine you previously defined with the add_processors command or received via a job scheduler. The hostname choices are as follows:

  machine_name — A string that specifies the host machine by its network name.

  LOCALHOST — A literal that specifies the host machine is the machine on which you invoked the tool.

  IPaddress — A string that specifies the host machine by its IP address.

- : *cpus*

  An optional colon (:) and positive integer pair that specifies the number of processes to delete on the particular host machine.

Example

The following example begins by reporting the distributed ATPG status. It then discontinues all the slave processes currently running on one remote host (nemo) and one of the slave processes running on the other remote host (ahab):

report_processors

```
hosts/processors   arch      CPU(s)     %idle    free RAM    process size
----------------  -------  -----------  -----  ------------  ------------
ace   (master)    x86      2 x 2.2 GHz    81%    8393.52 MB      20.07 MB
nemo           1  x86      2 x 2.0 GHz    98%     382.33 MB      18.78 MB
               2                                               18.78 MB
               3                                               18.78 MB
               4                                               18.78 MB
ahab           1  x86      1 x 1.7 GHz    99%     334.98 MB      18.78 MB
               2                                               18.78 MB
master and 6 processors running.
```

delete_processors nemo ahab:1

```
//  Deleted host nemo:4
//  Deleted host ahab:1
//  Total processors: 1
//  Note: Freeing 1 'Tessent FastScan' license.
```

report_processors

```
hosts/processors   arch      CPU(s)     %idle    free RAM    process size

delete_read_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

delete_read_controls ***primary_input_pin***... | **-All**

Description

Removes the read control line definitions from the specified primary input pins.

The delete_read_controls command deletes read control lines defined with the add_read_controls command. You can delete the read control line definitions for specific pins or for all pins.

Arguments

- ***primary_input_pin***

  A repeatable string that specifies a list of primary input pins from which you want to delete any read control line definitions.

- **-All**

  A switch that deletes the read control line definitions for all primary input pins.

Example

The following example deletes an incorrect read control line, then redefines that read control line with the correct off-state:

```
add_read_controls 0 r1 r2
delete_read_controls r1
add_read_controls 1 r1
set_system_mode analysis
```

Related Commands

add_read_controls

report_read_controls

delete_register_value

Context: all contexts

Mode: setup

Usage

delete_register_value { **-All** | ***value_name*** ...}

Description

Deletes all or a specified register value variable specified with the add_register_value command.

See "Serial Register Load and Unload for LogicBIST and ATPG" in the *Tessent Shell User's Manual* for complete information.

Arguments

- **-All**

  A required switch that deletes all register value variables.

- ***value_name*** ...

  A required repeatable string that deletes a named ***value_name***.

Example

The following example deletes all register value variables:

```
delete_register_value -all
```

Related Commands

add_register_value
set_register_value
report_register_value

delete_scan_chains

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_scan_chains ***chain_name***... | **-All**

Description

Removes the specified scan chain definitions from the scan chain list.

The delete_scan_chains command deletes scan chains defined with the add_scan_chains command. You can delete the definitions of specific scan chains or of all scan chains.

dft -scan Details

When you remove a scan chain definition, it is only the definition you are removing, not the scan chain itself.

Arguments

- ***chain_name***

  A repeatable string that specifies the names of the scan chain definitions that you want to delete.

- **-All**

  A switch that deletes all scan chain definitions.

Example

The following example defines several scan chains, adding them to the scan chain list, then deletes one of the scan chains:

```
add_scan_chains chain1 group1 indata2 outdata4
add_scan_chains chain2 group1 indata3 outdata5
add_scan_chains chain3 group1 indata4 outdata6
delete_scan_chains chain2
```

Related Commands

add_scan_chains

report_scan_chains

delete_scan_groups

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

delete_scan_groups ***group_name***... | **-All**

Description

Removes the specified scan chain group definitions from the scan chain group list.

The delete_scan_groups command deletes scan chain groups defined with the add_scan_groups command. You can delete the definitions of specific scan chain groups or of all scan chain groups.

When you delete a scan chain group, the tool also deletes all scan chains within the group.

Arguments

- ***group_name***

  A repeatable string that specifies the names of the scan chain group definitions that you want to delete.

- **-All**

  A switch that deletes all the scan chain group definitions.

Example

The following example defines two scan chain groups, adding them to the scan chain group list, then deletes one of the scan chain groups:

```
add_scan_groups group1 scanfile1
add_scan_groups group2 scanfile2
delete_scan_groups group1
```

Related Commands

add_scan_groups

report_scan_groups

delete_scan_instances

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_scan_instances {***pathname***… | ***instance_expression*** [-INStance | -Control_signal | -Module]} | **-All**

Description

Removes the specified, sequential instances from the user-identified scan instance list.

The delete_scan_instances command deletes sequential instances, instances specified by control signals, or all instances within the specified module that were previously added to the scan instance list by using the add_scan_instances command. You can delete either a specific list of instance names or all instances.

You can also use this command to remove an exception status from an instance, that you added using the add_scan_instances command, which allowed the tool to convert the instance into a scan cell even though it violated the S4 rule. In this case, although the instance is converted back into a non-scan instance, the effects of its previous unknown state on downstream instances is not reset.

User-identified scan instances result from using the add_scan_instances or add_scan_models commands.

If you issue an insert_test_logic command after removing an instance from the user-identified scan list with the delete_scan_instances command, the tool then has the option of including it in the system-identified scan instance list.

Arguments

- ***pathname***

  A repeatable string that specifies the pathnames of the instances or control signals (that control instances) that you want the tool to delete from the user-identified scan instance list. The pathnames must be user-identified scan instances or control signals (that control instances), which you previously selected with the add_scan_instances command.

- ***instance_expression***

  A string representing a list of instances within the design. The string instance_expression is defined as:

  { string | string * } ...

  The asterisk (*) is a wildcard that allows you to match many instances in a design. Any expression that does not contain an asterisk (*) will match exactly zero or one instance.

  This argument does not support pathnames to objects below the instance level of an ATPG library model. You can use a pathname expression to select several instances and the tool will then delete_scan_instances for all the pins on those instances; but if the expression

specifies a location below the instance level of an ATPG library model, the tool will issue an error message.

- -INStance | -Control_signal | -Module

  A switch that specifies whether the pathnames are instances, pins (control signals), or modules. An example Verilog module is “module clkgen (clk, clk_out, …)” where clkgen is the module name. You can only use the -*Control_signal* option in analysis mode. The default is -Instance.

- **-All**

  A switch that specifies to delete all instances from the user-identified scan instance list. This switch does not affect the instances in the system-identified scan instance list.

Examples

The following example deletes an extra sequential scan instance that was defined to be treated as a scan cell; thus, the deleted instance is no longer included in the user-identified scan instance list:

```
add_scan_instances i_1006 i_1007 i_1008
delete_scan_instances i_1007
```

Related Commands

add_scan_instances

report_seq_transparent_procedures

delete_scan_models

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_scan_models ***model_name***… | **-All**

Description

Removes the specified sequential models from the scan model list.

The delete_scan_models command deletes all instances of the sequential models that you specify. This includes removing all instances of the model_name from the user-identified scan instance list. You can delete a specific list of sequential models or all the models.

There are two ways that sequential instances can be identified for scan: system and user. You can explicitly identify scan instances with either the add_scan_instances or the add_scan_models commands (user-identified). The tool also selects the sequential instances automatically by targeting as many candidates as possible

If you issue an insert_test_logic command after removing a model from the user-identified scan list with the delete_scan_models command, the tool then has the option of including any of the instances of that model in the system-identified scan instance list.

To display the current scan model list, use the report_scan_models command.

Arguments

- ***model_name***

  A repeatable string that specifies the model names that you want to delete from the scan model list and user-identified scan instance list. Enter the model names as they appear in the DFT library.

- **-All**

  A switch that specifies to delete all models from the scan model list and all instances from the user-identified scan instance list.

Examples

The following example deletes an extra added sequential scan model; thus, the deleted model is no longer included in the scan model list:

```
add_scan_models d_flip_flop1 d_flip_flop2
delete_scan_models d_flip_flop2
```

Related Commands

delete_scan_partitions

Context: dft -scan

Mode: setup, analysis

Usage

delete_scan_partitions {***object_name...*** | **-All**}

Description

Deletes the user-specified scan partitions.

It does not delete the default scan partition, default_scan_partition. The sequential cells whose scan partitions are deleted are placed back into the default scan partition.

Arguments

- ***object_name***

  A required repeatable string that specifies the names of the scan partitions to remove.

- **-All**

  A required switch that specifies to remove all the user specified scan partitions. This option does not remove the default scan partition that the tool creates, default_scan_partition.

Examples

The following example adds three scan partitions. The scan partitions are then deleted, first partially, then completely.

```
add_scan_partition  part_1  -instance umodA
add_scan_partition  part_2  -instance umodB umodC
add_scan_partition  part_3  -instance umodD
delete_scan_partitions  part_2
report_scan_partitions

report_scan_partitions

----------------------------------------------------------------------
ScanPartitionName    TotalNumCells/ScannableCells  Members
----------------------------------------------------------------------
default_scan_partition        15480/400           <all_remaining_cells>
----------------------------------------------------------------------
```

Related Commands

add_scan_partition

report_scan_partitions

delete_scan_pins

Context: dft -scan

Mode: setup, analysis

Usage

delete_scan_pins ***chain_name***… | **-All**

Description

Removes any previously assigned scan input, output, and clock names from the specified scan chains.

The delete_scan_pins command removes user-specified names of the scan input and scan output pins of the scan chains that you previously assigned with the add_scan_pins command. You can use the report_scan_pins command to display all added scan input and output pin names for each scan chain.

Arguments

- ***chain_name***

  A repeatable string that specifies the names of the scan chains from which you want the tool to remove the associated pins.

- **-All**

  A switch that removes all added scan pin names from all scan chains.

Examples

The following example removes previously-assigned scan chain input and output names for chain1:

```
add_clocks 0 clk
set_system_mode analysis
add_scan_pins chain1 si so
add_scan_pins chain2 si1 so1
delete_scan_pins chain1
insert_test_logic
```

Related Commands

report_scan_pins

delete_simdut_fault

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

delete_simdut_fault **-signal** ***signal_name***

Description

Removes the injected stuck-at fault at the specified signal.

Arguments

- **-signal** ***signal_name***

  A required switch and string pair that specifies the name of a signal from the Verilog netlist.

Example

The following example removes an injected stuck-at fault from the SIMDUT_TB.CHIP.memory00.q_a signal.

```
delete_simdut_fault -signal SIMDUT_TB.CHIP.memory00.q_a
```

Related Topics

add_simdut_fault

delete_simulation_contexts

Context: all contexts

Mode: setup, analysis

Prerequisite: A flat model must currently exist

Usage

delete_simulation_contexts {*context_name*... | -all_user_defined }

Description

Deletes one or more user-defined simulation contexts.

The delete_simulation_contexts command allows you to delete one or multiple or all user-defined simulation contexts.

Arguments

- *context_name*

  An optional string that defines the name of one or more simulation contexts. Note that you cannot use wildcard characters in the context_name. You also cannot delete any of the predefined context names listed in Table 7-40 on page 1648.

- -all_user_defined

  An optional switch that specifies all user-defined simulation contexts.

Example 1

The following example lists all of the user-defined simulation contexts and then deletes them:

```
SETUP> get_simulation_context_list  -user_defined
{myContext1 myContext2 myContext3}

SETUP> delete_simulation_contexts -all_user_defined
SETUP> get_simulation_context_list -user_defined
{ }
```

Example 2

The following example lists all of the user-defined simulation contexts and then deletes two of them:

```
SETUP> get_simulation_context_list  -user_defined
{myContext1 myContext2 myContext3}

SETUP> delete_simulation_contexts { myContext2 myContext3 }
SETUP> get_simulation_context_list -user_defined
{ myContext1 }
```

Related Commands

set_current_simulation_context

delete_simulation_forces

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

delete_simulation_forces {***obj_spec*** **|** -all }

Description

Removes forces from one or more gate_pin objects.

The delete_simulation_forces command removes simulation forces from the specified gate_pin object(s). When this command removes a simulation force, the tool immediately propagates the values on the driving gate_pin objects to keep the circuit in a consistent state.

This command is allowed for user-defined contexts only.

Arguments

- ***obj_spec***

  An optional value that specifies one or more gate_pin objects.

- -all

  An optional switch that removes all simulation forces on all gate_pin objects within the current simulation context.

Example

The following example shows the effect of adding a force and then removing all forces:

ANALYSIS> **set_current_simulation_context myContext**
ANALYSIS> **add_simulation_force [get_gate_pins I1] -value 1**
ANALYSIS> **report_simulation_forces**

```
Value   Object
------  ------
1       I1
```

ANALYSIS> **delete_simulation_forces -all**
ANALYSIS> **report_simulation_forces**

Related Commands

simulate_forces

delete_sub_chains

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_sub_chains **-All** | {***object_name*** [*subchain_name*]
[-Module | -Instance | -Library_model]}

Description

Removes scan subchains previously defined with the add_sub_chains command. Use the report_sub_chains command to display the currently defined scan subchains.

Arguments

- **-All**

  A switch that removes all scan subchains.

- ***object_name***

  A string that specifies either the pathname of an instance, or the name of a module or library model. If you specify an instance, you must also use the -Instance switch. If you specify a library model, you must also use the -Library_model switch.

- *subchain_name*

  An optional string that specifies the name of a pre-existing scan subchain to delete. If you do not specify a *subchain_name*, all subchains in the specified *object_name* are deleted.

- -Module

  An optional switch that specifies the object_name is a module. This is the default.

- -Instance

  An optional switch that specifies the object_name is an instance.

- -Library_model

  An optional switch that specifies the object_name is a library model.

Examples

The following example deletes the subc1 subchain from the blkA module:

```
add_sub_chains blkA subc1 si1 so1 10 mux_scan -sen_core sen1 -subclock sclk -module
add_sub_chains blkA subc2 si2 so2 30 mux_scan -sen_core sen2 -subclock mclk -module
delete_sub_chains blkA subc1
```

Related Commands

add_sub_chains

report_sub_chains

delete_subchain_clocks

Context: dft -scan, dft -test_points

Mode: setup

Usage

delete_subchain_clocks ***subchain_name clock_name***

Description

Deletes subchain clocks previously defined with the add_subchain_clocks command.

Arguments

- ***subchain_name***

  A required string that specifies the name of a subchain.

- ***clock_name***

  A required string that specifies the name of a subchain clock.

Examples

The following example adds, reports, and deletes a subchain clock:

add_sub_chains MULTIBITSFF3 chain1 SI SO 4 mux_scan S library_model
add_subchain_clocks chain1 0 RESET -reset
add_subchain_clocks chain1 0 SET -set
add_subchain_clocks 0 CK -first_cell_clock -leading_edge
add_subchain_clocks 0 CK -last_cell_clock -leading_edge
report_subchain_clocks chain1

```
// clock name type         off_state   edge
// ---------- ----         ---------   -----
// RESET     reset             0
// SET       set               0
// CK        first cell clock  0       leading edge
// CK        last cell clock   0       leading edge
```

delete_subchain_clocks chain1 CK
report_subchain_clocks chain1

```
// clock name type  off_state  edge
// ---------- ----- --------- ------
// RESET       reset 0
// SET         set   0
```

Related Commands

add_subchain_clocks

report_subchain_clocks

delete_subchain_groups

Context: dft -scan

Mode: setup, analysis

Usage

delete_subchain_groups ***subchain_group_name*** … | **-All**

Description

Removes a scan subchain group.

The delete_subchain_groups command removes subchain groups added by means of the add_subchain_group command. To determine whether there are any current scan subchain groups, use the report_subchain_groups command.

Arguments

- ***subchain_group_name***

  A repeatable string that specifies the names of the subchain group definitions to be deleted.

- **-All**

  A switch that removes all subchain group definitions.

Examples

The following example removes a subchain group definition:

add_subchain_group subchaingroup1 subchain1 subchain2 -fixed
add_subchain_group subchaingroup2 subchain3 subchain4 -flexible
report_subchain_groups

```
-----------------------------------------------
SubchainGroupName   Type      ListOfSubchains
-----------------------------------------------
subchaingroup1      fixed     subchain1
                              subchain2
subchaingroup2      flexible  subchain3
                              subchain4
```

delete_subchain_group subchaingroup1

Related Commands

add_subchain_group

delete_test_points

Context: dft -test_points

Mode: setup

Usage

delete_test_points [**-control** | **-observe**] [**-location** ***pin/port_spec*** | **-all**]

Description

Removes the specified test point definitions.

If you do not specify -control or -observe with either the -location *pin/port_spec* or the -all option, the tool removes all the control and observe test points. If you enter the command without any arguments, the tool removes all the control and observe test points.

This command removes both user-defined and system-defined test points. You can create user-defined test points with the add_control_points and add_observe_points commands.

Arguments

- **-all**

  An optional switch that removes the control and/or observe test points from all locations.

- **-control**

  An optional switch that removes the control test points from the specified locations.

- **-observe**

  An optional switch that removes the observe test points from the specified locations.

- **-location** ***pin/port_spec***

  An optional switch and string that specifies a pathname to the control and/or observe test points to delete.

  pin/port spec can be the name of a pin/port, a Tcl list of pins/ports, or a collection of pin/port objects.

Examples

The following example removes test points:

```
delete_test_points /I_6_16/cp /I_7_16/q
```

The delete_test_points command only specifies the pathnames of the test points, not the type. This example includes both control and observe test points and deletes them by default.

Related Commands

add_tied_signals
report_test_logic
report_test_points
add_input_constraints
set_test_point_insertion_options

delete_tied_signals

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

delete_tied_signals {***floating_object_name***... | **-All**} [-Pin]

Description

Removes the assigned (tied) value from the specified floating nets or pins.

The delete_tied_signals command deletes the tied values assigned with the add_tied_signals command. You can display a list of tied signals using the report_tied_signals command.

Whenever you delete tied values from nets or pins, be sure to re-add any necessary values before performing another simulation. If you do not add required tied values to floating nets or pins, the tool displays a warning. The warning states that the design has floating nets or pins and assumes they are tied to the default value; you must set the default value using the set_tied_signals command.

Arguments

- ***floating_object_name***

  A repeatable string that specifies the names of the tied floating nets or pins whose tied values you want to delete.

  If you do not specify the -Pin option, the tool assumes floating_object_name is a net name. If you specify a full net pathname, the tool deletes only the specified instance-based blackbox tied signal. If you specify the -Pin option, it assumes the floating_object_name is a pin name.

- **-All**

  A switch that deletes the tied values from all tied floating nets or pins. This also includes all instance-based blackbox tied signals.

- -Pin

  A switch specifying that the *floating_object_name* argument that you provide is a floating pin name.

Example

The following example deletes the tied value from the user-class tied net “vcc”; thereby leaving “vcc” as a floating net:

```
add_tied_signals 1 vcc vdd
delete_tied_signals vcc
```

Related Commands

add_tied_signals
delete_black_boxes
report_tied_signals
set_tied_signals

delete_write_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup

Usage

delete_write_controls ***primary_input_pin***... | **-All**

Description

Removes the write control line definitions from the specified primary input pins.

The delete_write_controls command deletes write control lines defined with the add_write_controls command. You can delete the write control line definitions for specific pins or for all pins.

Arguments

- ***primary_input_pin***

  A repeatable string that specifies a list of primary input pins from which you want to delete any write control line definitions.

- **-All**

  A switch that deletes the write control line definitions for all primary input pins.

Example

The following example deletes an incorrect write control line, then re-adds that write control line with the correct off-state:

```
add_write_controls 0 w1 w2
delete_write_controls w1
add_write_controls 1 w1
set_system_mode analysis
```

Related Commands

add_write_controls

report_write_controls

diagnose_failures

Context: patterns -scan_diagnosis

Mode: analysis

Prerequisites: The read_patterns command must be set to a pattern source.

Usage

diagnose_failures {***failure_filename*** | **-Internal**} [-Output *report_filepath*] [-Csv *csv_filename*] [-Replace] [-Faulty_chain {*faulty_chain_name faulty_chain_type*}...]

Description

Diagnoses the failures in the specified failure file.

The diagnose_failures command performs a diagnosis of the failing scan and chain test patterns in the specified failure file, or diagnosis of the IDDQ patterns in the specified failure file.

For scan and chain test patterns, you must translate the ATE failure log into a failure file as described in the "Guidelines for Preparing the ATE Failure File" section in the *Tessent Diagnosis User's Manual*. For IDDQ patterns, see "IDDQ Failure File Format" for the required failure file format.

It is critical that the data in the test patterns, flattened netlist, and failure file be synchronized for diagnosis. For more information, see "Input File Requirements" in the *Tessent Diagnosis User's Manual*.

For complete information on running diagnosis and interpreting the results, see the *Tessent Diagnosis User's Manual*.

Arguments

- ***failure_filename***

  A required string that specifies the name of the file that contains the failing test pattern information for diagnosis. This file can use either the pattern-based or cycle-based format as described in the "Guidelines for Preparing the ATE Failure File" section in the *Tessent Diagnosis User's Manual*.

  For IDDQ diagnosis, specify the IDDQ failure file. See "IDDQ Diagnosis" for more information.

- **-Internal**

  An required switch that directs the tool to use the in-memory failure file. You must issue a read_failures command before you use the diagnose_failures -internal command. See "Diagnosis Improvements Through Additional Pattern Generation" in the *Tessent Diagnosis User's Manual* for complete information.

- -Output *report_filepath*

  An optional switch and string pair that directs the tool to write the diagnostic report in ASCII format to the specified file. By default, the diagnostic report displays on screen.

- -Csv *filename*

  An optional switch and string pair that directs the tool to write the diagnostic report in Comma Separated Value (CSV) format to the specified file. The CSV format does not include the list of failing patterns for each symptom. By default, the diagnostic report displays on screen.

- -Replace

  An optional switch that directs the tool to overwrite existing diagnostic report files in either ASCII or CSV format. By default, the tool will not overwrite existing files.

- -Faulty_chain *faulty_chain_name faulty_chain_type*

  An optional switch and repeatable string and literal pair that allows you to run diagnosis on specified chain failures in addition to the scan failures contained in a failure file.

  faulty_chain_name — string that specifies the name of the faulty chain.

  fault_type — literal that specifies the fault type associated with the faulty chain. Valid fault types include:

  STUCK_AT_1

  STUCK_AT_0

  SLOW_TO_FALL

  SLOW_TO_RISE

  SLOW

  FAST_TO_RISE

  FAST_TO_FALL

  FAST

  INDETERMINATE — specifies the fault type can not be determined.

Example 1

The following example: sets *pattern_file1* as the external test pattern source, injects a stuck-at-0 fault into the design, writes out a failure file named *fail_patterns*, and performs a diagnosis of the failing patterns in the *fail_patterns* file.

```
set_system_mode analysis
read_patterns pattern_file1
write_failures fail_patterns i_1006/i1 -stuck_at 0

//  failing_patterns=9  simulated_patterns=36  simulation_time=0.00 sec

diagnose_failures fail_patterns

...
```

Still using the external test pattern source file *pattern_file1*, the following example: injects an additional stuck-at-0 fault into the *fail_patterns* failure file, performs a diagnosis of the failing patterns in the *fail_patterns* file, and sends the report to a file named *fail_diags*.

write_failures fail_patterns i_1005/i1 -stuck_at 0 -replace

```
//  failing_patterns=4  simulated_patterns=36  simulation_time=0.00 sec
```

diagnose_failures fail_patterns -output fail_diags

Example 2

The following example loads patterns from two files into the tool external pattern database and performs two separate diagnoses using the default settings. The example writes the resulting reports to files instead of displaying them onscreen. The failure file, *scan_failure_file*, contains only a scan test section ("scan_test" keyword followed by scan test fails), so the tool performs only a scan diagnosis for that file. The second file, *chain_failure_file*, contains a chain test section ("chain_test" keyword followed by chain test fails) as well as a scan test section. The tool performs only a chain diagnosis for that file.

read_patterns pat_file1
read_patterns pat_file2 -append
diagnose_failures scan_failure_file -output scan_diag.ascii -csv scan_diag.csv
diagnose_failures chain_failure_file -output chain_diag.ascii -replace

Example 3

The following example first performs chain diagnosis on a failure file that contains a chain_test section. The example next attempts a diagnosis of a failure file that contains no chain_test data; however, because the set_diagnosis_options command is set to chain mode, the tool skips this diagnosis.

read_patterns pat_file1
set_diagnosis_options -mode chain
diagnose_failures chain_failure_file -output chain_diag.ascii -replace
diagnose_failures scan_only_failure_file -output scan_diag.ascii -csv scan_diag.csv

```
//  Error: Cannot identify faulty chains. Please either use chain test
//    patterns or specify faulty chains.
```

Example 4

The following example sets the external test pattern source to *pattern_file1*, runs diagnosis on the chain_foo chain failure and the failed patterns failure file.and runs diagnosis on the *chain_foo* chain failure and the *failed cycles* failure file.

set_system_mode analysis
read_patterns pattern_file1
diagnose_failures failed_cycles -faulty_chain chain_foo FAST_TO_FALL

set_fault_type
write_flat_model
write_failures

display_specification

Context: dft

Mode: setup, analysis

Usage

display_specification [*id*] [-design_name *design_name*] [-create]

Description

Displays the DftSpecification(design_name,id) configuration data in a tab of the Configuration Tree window of DFTVisualizer.

You can create a DftSpecification from scratch in DFTVisualizer by using the -create option, or also modify an existing DftSpecification.

When only one DftSpecification wrapper is defined in memory, you do not need to supply any arguments; the tool automatically displays the single DftSpecification wrapper.

You define, or modify, DftSpecifications using the Configuration window in DFTVisualizer. This window provides a graphical user interface for inserting Mentor DFT IP into existing designs. For information on using the Configuration window in DFTVisualizer, refer to the section "Generation of a DFT Specification" in the *Tessent IJTAG User's Manual*.

Arguments

- *id*

  An optional string that specifies the DftSpecification wrapper to be displayed. As described in the DftSpecification wrapper syntax, the wrapper is identified by the two strings design_name and id. If you only have one DftSpecification wrapper present in memory that matches DftSpecification(design_name,*), you can omit the id from the display_specification command. However, if several DftSpecification wrappers matching DftSpecification(design_name,*) exist in memory, you must specify the appropriate id when executing the display_specification command. Refer to the description of the -design_name option to understand how the value of design_name is obtained.

- -design_name *design_name*

  An optional switch and string pair that specifies the design_name value used to identify the DftSpecification wrapper. The -design_name value defaults to the current design if it has been set with the set_current_design command. If the current design has not been set, it is extracted from the DftSpecification wrapper existing in memory.

  When the id is specified, if exactly one wrapper matches "DftSpecification (*,<id>)" in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified unless the -create option is specified. When the id is not specified, if exactly one wrapper matches "DftSpecification (*,*)" in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified.

- -create

  An optional switch that disables the existence check of the DftSpecification wrapper and specifies to create and display an empty DftSpecification wrapper. If either of the id or -design_name options are not specified, their values are determined using the heuristic described in the id and -design_name options description. If the tool cannot determine the id, the default is “rtl” in the dft -rtl context and “gate” in the dft -no_rtl context. If the tool cannot determine the design_name, it is set to “?” in the created file which you can then modify in DFTVisualizer. If you do not change the “?” to a valid design name, the tool will generate an error when you attempt to process the DftSpecification.

Example 1

The following example reads a DftSpecification from a file and displays it in DFTVisualizer.

```
set_context dft -rtl
read_config_data ./my_design.dft_spec_rtl
display_specification
```

Example 2

The following example creates an empty DftSpecification and displays it in DFTVisualizer, allowing the user to add its content using the DFTVisualizer graphical user interface. The created DftSpecification wrapper is named “DftSpecification(mydesign,rtl)”. The design_name is taken from the name of the current design. The id defaults to “rtl” because the command was called inside the dft -rtl context.

```
set_context dft -rtl
read_verilog mydesign.v
set_current_design mydesign
display_specification
```

Related Commands

process_dft_specification

display_diagnosis_report

Context: patterns -scan_diagnosis

Mode: analysis

Prerequisites: This command can only operate on a diagnosis report file written out using the diagnose_failures command with the -Output switch.

Usage

display_diagnosis_report ***diagnose_failures_output_filename***

DFTVisualizer Menu Path:
Tools > Diagnosis Report

Description

Opens a diagnosis report in which you can click symptoms and suspect locations to add related gates to the DFTVisualizer Debug window.

The display_diagnosis_report command opens the specified diagnosis report file in File Viewer of DFTVisualizer. In the displayed report, each symptom and all suspect locations (pin and net pathnames) show up as active links. Clicking a suspect's pin_pathname link adds the gate associated with that pin to the DFTVisualizer Debug window. Clicking a suspect's net_pathname link adds all the gates connected to that net. Clicking a symptom link adds all the gates with pins in that symptom's suspect list.

Refer to "Diagnosis Reporting" in the *Tessent Diagnosis User's Manual* for a detailed description of the types of information contained in the diagnosis report.

Arguments

- ***diagnose_failures_output_filename***

  A required string that specifies the pathname of a diagnosis report file written out using the diagnose_failures -Output command.

Example

The following example performs scan diagnosis using the set of ATPG patterns in the pattern file *pat_file1* and the failure information in the failure file *scan_failure_file*, writing the diagnosis report in ASCII format to the file *scan_diag.ascii*. The example then opens DFTVisualizer if it is not already open and opens the diagnosis report in the File Viewer.

```
read_patterns pat_file1
diagnose_failures scan_failure_file -output scan_diag.ascii -replace
display_diagnosis_report scan_diag.ascii
```

Related Commands

diagnose_failures

set_diagnosis_options

display_message

Context: unspecified, all contexts

Mode: all modes

Usage

display_message **string** [-error | -warning | -info | -note]

Description

Sends a message to the specified message stream.

The string can contain \n to break the message into multiple lines. Messages sent in the message stream are prefixed with an "// Error: ", "// Warning:" , "//" , "//" or "//Note:" string as appropriate, and successive lines are automatically indented.

The output of Tcl commands such as **puts** is also redirected to the screen and/or to a log file as with any other tool output.

Arguments

- string

  A required string that specifies the message to be sent to the message stream. The string supports the use of the newline character sequence "\n" to break the message into multiple lines.

- -error

  An optional literal that specifies to send a message into the error stream. This message does not interrupt the execution of the script. You can issue multiple error messages and then terminate the script using a {return -code error "string"} command. This return code causes the dofile to abort unless you have specified set_dofile_abort off.

- -warning

  An optional literal that specifies to display a warning.

- -info

  An optional literal that specifies to display an information note. The message is prefixed by a double slash "//".

- -note

  An optional literal that specifies to display a note.

Example

The following example issues two error messages and then stops the invocation of the current Tcl command using a Tcl return -code error command.

```
display_message "this value is wrong" -error
display_message "this other value is also wrong" -error
return -code error
```

Related Commands

register_tcl_command

unregister_tcl_command

dofile

Context: unspecified, all contexts

Mode: all modes

Usage

dofile ***filename*** [-History]

Description

Executes the commands contained within the specified file.

The dofile command sequentially executes the commands contained in a specified file. This command is especially useful when you must issue a series of commands. Rather than executing each command separately, you can place them into a file in their desired order and then execute them by using the dofile command. You can also place comment lines in the file by starting the line with a double slash (//); the tool handles these lines as comments and ignores them.

The dofile command sends each command expression (in order) to the tool which in turn displays each command line from the file before executing it. If the tool encounters an error due to any command, the dofile command stops its execution, and displays an error message. You can enable the dofile command to continue regardless of errors by setting the set_dofile_abort command to Off.

The dofile command is very similar to the Tcl source command except the dofile command has the following additional usability features:

- Loads relative paths called with dofile <RelativeFilePath> relative to the position of the dofile containing the dofile command.

  You must use the same syntax when using the source command as shown here: source [file dirname [info script]]/<RelativePathToFile>. When the source command is used, the file is processed purely by the Tcl shell.

- Accepts // as comments, as well as #.

- Automatically escapes [#] and [#:#] entries in bus names.

Arguments

- ***filename***

  A required string that specifies the name of the file that contains the commands that you want the tool to execute.

- -History

  An optional switch that specifies for the tool to add the commands from a dofile to the command line history list. By default, the commands in a dofile are not inserted into the history list, but the dofile command itself is added to the list.

Example

The following example executes, in order, all the commands from the file *command_file*:

```
dofile command_file
```

The command_file may contain any Tcl or application command available. An example of a command_file is as follows:

```
foreach_in_collection net [get_nets u1/*] {
    if {[sizeof_collection [get_fanins $net]] == 0} {
        delete_connections [get_fanouts $net -stop_on pin]
        delete_nets $net
    }
}
```

Related Commands

history

set_dofile_abort

echo

Context: unspecified, all contexts

Mode: all modes

Usage

echo ***"string"*** [{> | >>} *file_pathname*]

Description

Issues a user-defined string to the transcript.

The echo command issues a user-defined string to the transcript or to a pathname, if you use one of the file redirection operators.

Note

Commands that use either the > or >> file redirection operator are first checked for correctness. Syntax errors are reported to the display prior to the command's execution. The redirection operator does not hide these errors.

Arguments

- ***string***

  A required string. The string that you want echoed to the transcript. Double quotes are required if the string contains spaces or special characters.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example redirects output from several commands into a single output file, *my_scan_report*. The first command creates or replaces the *my_scan_report* file. The second and following commands append to the same file.

```
echo "----------- scan cells ------------" > my_scan_report
report_scan_cells >> my_scan_report
echo "----------- scan chains ----------" >> my_scan_report
report_scan_chains >> my_scan_report
```

execute_cdp_test

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

execute_cdp_test ***test_name*** [-collect_data_type_list variable]

Description

Executes the specified test using the currently connected tester.

By default, this command returns pass/fail results for the associated test procedure. When you specify -collect_failures variable, the tool collects the failing data during test execution and returns the failing data in a tabulated format. The tool provides the failing data with respect to the ReadVar variables originally specified in the PDL that you used to generate the pattern.

When you are using SimDUT as your tester, the tool converts the test pattern file to simulation events, and then the Verilog simulator returns the failing information to SimDUT.

Refer to "Executing an IJTAG Test Pattern" in *Tessent SiliconInsight User's Manual for Tessent Shell* for a sample usage scenario.

Arguments

- ***test_name***

  A required string that specifies the name of the test you want to execute.

- -collect_data_type_list variable

  An optional switch and literal that specifies to execute the test and return variable failures.

Example 1

The following example executes test1 on the DUT and returns the results for the collect_failures procedure for the test pattern associated with test1.

execute_cdp_test test1 -collect_data_type_list variable

```
//  command: execute_cdp_test test1 -collect_data_type_list variable
//  Test 'test1' failed.
//  Variable failures and unmapped failures of pattern
// 'DLV2_1S0_ETMemory_Full.svf' :
//
//  PatternSet  Variable                        Pin  Expected
//                                                     Actual
//  ----------  ----------------------------  ---  --------
//        main             BP2_WIR.IR_STATUS2  TDO        b1
//                                                        b0
//  ----------  ----------------------------  ---  --------
//        main        BP2_WIR.IR_STATUS1.DONE  TDO        b1
//                                                        b0
//  ----------  ----------------------------  ---  --------
//        main  BP2_WDR.WBP1_INST_POINTER_REG  TDO   b000000
//                                                   b001001
```

```
//  ----------  ----------------------------  ---  --------
//        main       BP2_WDR.WBP1_A_ADD_REG_Y  TDO     b0000
//                                                    b1111
//  ----------  ----------------------------  ---  --------
//        main       BP2_WDR.WBP1_A_ADD_REG_X  TDO     b0000
//                                                    b1000
//  ----------  ----------------------------  ---  --------
//        main       BP2_WDR.WBP1_GO_ID_REG10  TDO        b0
//                                                       b1
//  ----------  ----------------------------  ---  --------
```

Example 2

The following command returns the pass/fail results for the test pattern associated with test2.

execute_cdp_test test2

```
command: execute_cdp_test test2
Test 'test2' failed.
```

add_cdp_test

launch_sid_tester

execute_gpib_command

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

execute_gpib_command ***command*** **-address** ***gpib_address*** [-read_result [-timeout *read_timeout_period*]]

Description

Note

Using this command assumes that you have configured the equipment on the GPIB as described in General Purpose Interface Bus (GPIB) standard IEEE-488. It also assumes that the GPIB instrument supports the GPIB commands you specify.

Allows you to control and program GPIB equipment.

In Tessent SiliconInsight, you generally use GPIB equipment to control power supplies and clock generators for testing purposes. However, you may also control any GPIB instrument—such as a PMU, temperature control, or digital IO—as long as it supports the GPIB standard.

You must connect the GPIB equipment to a USB-to-GPIB adaptor, which you then connect to the performance board.

Combining this command with the execute_cdp_test and add_cdp_test commands enables you to generate detailed programs for debugging and characterizing DUTs. Refer to "Executing an IJTAG Test Pattern" in *Tessent SiliconInsight User's Manual for Tessent Shell* for a sample usage scenario.

Arguments

- ***command***

  A required string that specifies a GPIB command and arguments. The GPIB command must be a valid GPIB command that is supported by the targetted GPIB instrument. Specify the command between quotes.

- **-address** ***gpib_address***

  A required switch and integer pair that specifies the address of the targeted GPIB equipment, where the *gpib_address* is an integer from 0 to 30. This switch enables execution of the GPIB command on the GPIB equipment configured to listen at the specified address.

- -read_result

  An optional switch that directs Tessent SiliconInsight to read the results that the GPIB equipment returns after it executes the specified GPIB command. Use this switch when the GPIB command is a query command, and you expect a query result from the GPIB

equipment. By default, Tessent SiliconInsight Desktop assumes that the GPIB command is a non-query command, and it does not read data from the GPIB equipment.

- -timeout *read_timeout_period*

  An optional switch and integer pair that specifies the maximum length of time (in milleseconds) to wait for the result of the specified command to appear on the GPIB before timing out. The default wait period is 2 seconds (2000 ms).

Example 1

The following command directs the tool to execute the SetVoltage 1.6V command on the GPIB instrument that is enabled at address 5.

execute_gpib_command “SetVoltage 1.6V” -address 5

Example 2

The following command directs the tool to execute the ReadCurrent command on the GPIB instrument that is enabled at address 12. The ReadCurrent command returns results, which Tessent SiliconInsight Desktop will read because you have specified the -read_result switch. The tool will wait no more than 500 ms for the results to appear.

execute_gpib_command “ReadCurrent” -address 12 -read_result -timeout 500

add_cdp_test

execute_cdp_test

Preparing the Computer for Tessent SiliconInsight Desktop

exit

Context: unspecified, all contexts

Mode: all modes

Usage

exit [-force] [*exitval*]

Description

Terminates the application tool program.

The **exit** command terminates the tool session and returns to the operating system. You should either save the current test patterns or modified design before exiting the tool.

If you are operating in interactive mode (not running a dofile) and you do not save the current test pattern set or modified design, the tool displays a warning message, and you are given the opportunity to continue the session and save the test patterns before exiting.

Arguments

- -force

  An optional argument that forces termination of the current tool session even though unsaved data may be lost.

- *exitval*

  An optional integer that specifies an exit code.

  This option can be used to return a non-zero value when exiting the tool. By default, when there's no error, “0” is returned to the caller while non-zero usually indicates an error condition. The specific value returned can be used to differentiate the type of condition that resulted in issuing the exit command.

Example

The following example quits the tool without saving the current test pattern set.

```
set_system_mode analysis
create_patterns
exit -force
```

expand_compressed_patterns

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Usage

expand_compressed_patterns [-CHAIN ***chain_name***...]
[-MAX_1hot_pattern ***pattern_number***] [-MAP_file ***map_filename***] [-REPlace]

Description

Expands compressed 1-hot patterns for better internal failing flop diagnosis.

See "1hot Compressed Pattern Expansion" in the *Tessent Diagnosis User's Manual* for complete information.

Arguments

- -CHAIN ***chain_name***...

  An optional switch and repeatable string that identifies the scan chain name(s) to process for 1-hot expansion.

- -MAX_1hot_pattern ***pattern_number***

  An optional switch and required integer that specifies the maximum number of patterns to produce during expansion. The default value is 1000. If this limit is exceeded, the tool stops command execution and prints a warning message that the limit was exceeded.

- -MAP_file ***map_filename***

  An optional switch and required string that specifies the map filename where 1-hot pattern-IDs, original pattern-IDs, and mapped channel information is saved. Use the -replace option to overwrite an existing map file.

- -REPlace

  An optional switch for overwriting an existing file.

write_patterns
set_pattern_filtering

extract_icl

Context: all contexts

Mode: all modes

Usage

extract_icl [-write_in_tsdb {on | off | (auto)}] [-design_identifier *string*]

Description

Checks the ICL connectivity rules between Ijtag instances and extracts the top-level ICL module.

An error is generated if an ICL module already exists for the top module (current design).

The command changes the context to patterns -ijtag and goes to the system mode analysis. If ICL extraction is successful, it returns the system mode and the context to what it was when the command was invoked. If ICL extraction fails due to one or more DRC errors, the system mode is left in setup mode and the context is left as patterns -ijtag to enable you to debug the DRC violations. Use the open_visualizer command to open the DFTVisualizer debug environment and debug the DRC violations.

Arguments

- -write_in_tsdb on | off | (auto)

  An optional switch and literal pair that controls whether the extracted ICL is automatically written out in the specified TSDB output directory. The TSDB output directory is specified with the set_tsdb_output_directory command and defaults to “tsdb_outdir”.

  With the default value of “auto”, the ICL file is only written if the directory <tsdb_outdir>/dft_inserted_designs/<current_design>_<design_id>.dft_inserted_design already exists. This directory is typically created by the process_dft_specification command prior to invoking the extract_icl command as shown in Example 1.

- -design_identifier *string*

  An optional switch and value pair that sets the design_identifier. You cannot use this option if you are using extract_icl immediately after the process_dft_specification command because the tool will automatically use the design id of the DftSpecification wrapper. You should use this option only in the rare case where you want to save the extracted ICL file in the TSDB directory, and you have not run the ICL extraction imediately following the DFT step. In this case, the tool will use the design identifier specified or inferred with the “set_context dft” command.

Example 1

The following example shows the use of the extract_icl command directly following the process_dft_specification command.

```
set_context dft -rtl
#commands to load design apprears here

set_current_design CoreA
set_design_level physical_block

set_system_mode analysis

create_dft_specification
process_dft_specification

extract_icl
```

Example 2

The following example shows the use of the extract_icl command as part of the “patterns -scan” context to extract the ICL network such that it can be used for test setup. For efficiency, it is recommended to extract the ICL only once after the DFT is completed, and to reuse the extracted ICL in all pattern -scan usage. ICL extraction may also not be possible after layout if the ICL modules were ungrouped during layout. The standard flow is to use the pre-layout ICL file extracted either on the RTL or netlist view for all subsequent pattern generation phases. Formal verification is typically used to verify that the functional mode, including the IJTAG network, was not affected by the layout process.

```
set_context patterns -scan
#commands to load design and cell library apprears here

set_current_design

extract_icl

set_test_setup_icall myproc1
```

filter_collection

Context: unspecified, all contexts

Mode: all modes

Usage

filter_collection ***base_collection expression*** [-regexp] [-nocase]

Description

Filters a previously created collection, resulting in a new collection.

In many cases, the commands that create collections support a -filter option, which performs filtering as part of the collection process. Usually this is a more efficient method of filtering. However, you may want to use the filter_collection command if you are filtering a large collection multiple times with different criteria.

The filter_collection command results either in a new collection that contains a subset of the objects in the input base_collection, or in an empty collection, which indicates that the expression filtered out all elements of the input base_collection.

Arguments

- ***base_collection***

  A required string that specifies the base collection to be filtered. This collection is copied to the resulting collection, and objects are removed if they are evaluated as false by the conditional expression.

- ***expression***

  A required string that specifies an expression with which to filter the collection. The attributes used within the equation must exist for the object types contained in the collection. Otherwise, an error is generated. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the matching patterns as a regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that specifies that the pattern match is case insensitive.

Example 1

The following example creates a collection of instances of type design.

set var [filter_collection [get_instances *] {type == "design”}]

```
{Adder1 Adder2}
```

Example 2

The following example starts with a collection of all instances and filters the collection based on an attribute_equation of user-defined attributes.

set var [filter_collection [get_instances] {myType1 || myType2 == “ABC"}]

The above example is equivalent to this:

set var [get_instances -filter {myType1 || myType2 == “ABC"}]

find_design_names

Context: all contexts

Mode: all modes

Usage

find_design_names ***name_pattern*** [-LOcal | -Hier]
[-Design | -NETList | -LIbrary | -All]
[-INStance | -Net | -Pin [INPut | OUtput | INOut | ALLIn | ALLOut] |
[[-Cell | -Module] -LISt_references]]
[{> | >>} *file_pathname*]

Description

Displays design object hierarchical names matched by an input string, which may include asterisk (*) or question mark (?) wildcard characters.

Arguments

- ***name_pattern***

  A required string, which may include asterisk (*) or question mark (?) wildcard characters.

- -LOcal

  An optional switch that matches wildcard characters within the current hierarchy level.

- -Hier

  An optional switch that matches the regular expression across hierarchy boundaries (for example, a* matches a1/b/c). This is the default.

- -Design

  An optional switch that matches only pathnames to objects at the topmost library cell level.

- -NETList

  An optional switch that matches objects from the top of the design down to the topmost library cell.

- -LIbrary

  An optional switch that matches objects within any level of library cells.

- -All

  An optional switch that specifies matches objects at all levels of the design. This is the default.

- -INStance

  An optional switch that matches only instance pathnames. This is the default.

- -Net

  An optional switch that matches only net pathnames.

- -Pin

  An optional switch that matches only pin pathnames (any pin direction). The following optional pin filters restrict which pins are matched:

  INPut — Match only input pin pathnames.

  OUtput — Match only output pin pathnames.

  INOut — Match only bidirectional pin pathnames.

  ALLIn — Match both input and bidirectional pin pathnames.

  ALLOut — Match both output and bidirectional pin pathnames.

- -Cell

  An optional switch that finds all library cell (model) names matching the specified regular expression.

- -Module

  An optional switch that finds all netlist module names matching the specified regular expression.

- -LISt_references

  An optional switch for use with -Cell or -Module that lists the pathnames of all instances in the current design that reference each cell or module matching the regular_expression.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following examples display object pathnames for various input wildcard strings, given a netlist with the following instance hierarchy:

```
/
   tiny_i
      U5
   ret_i
      intreg1_reg_0 ... intreg1_reg_31
      add_20
         U1_0 ... U1_3
      add_30
         U5 ... U12
      mul_18
         U5 ... U868
         FS
            U5 ... U33
      mul_19
         FS
```

```
            U5 ... U278
         U5 ... U181
      mul_22
         U5 ... U735
         FS
            U15 ...
```

and assuming the U5 instances all reference the following library cell:

```
model LSR2BUFA(Q, QN, S, R, G, SD, RD) (
   input(S, R, G, SD, RD) ()
   output(Q) (primitive = _buf UP1 (QT, Q);)
   output(QN) (primitive = _buf UP2 (QNT, QN);)
   intern(QT_int) (instance = LSI_LSR2 UD1 (QT_int, S, R, G, SD, RD);)
   intern(QNT_int) (instance = LSI_LSR2N UD2 (QNT_int, S, R, G, SD, RD);)
   intern(QT) (instance = LSI_NOTI UD3 (QT, QT_int);)
   intern(QNT) (instance = LSI_NOTI UD4 (QNT, QNT_int);)
)
```

Example 1

find_design_names /ret_i/add_2* -instance -design -hier

```
// Note: Matched 4 names
/ret_i/add_20/U1_0
/ret_i/add_20/U1_1
/ret_i/add_20/U1_2
/ret_i/add_20/U1_3
```

Example 2

find_design_names /ret_i/add_2* -instance -netlist -hier

```
// Note: Matched 5 names
/ret_i/add_20
/ret_i/add_20/U1_0
/ret_i/add_20/U1_1
/ret_i/add_20/U1_2
/ret_i/add_20/U1_3
```

Finds instance add_20 under /ret_i/, and also descends the hierarchy to find all netlist instances under /ret_i/add_20/.

Example 3

find_design_names /ret_i/add_2* -inst -netlist -local

```
// Note: Matched 1 names
/ret_i/add_20
```

This example shows that -Local does not descend the hierarchy to find more matches as the previous example does.

Example 4

find_design_names /ret_i/add_2* -ins -design -local

```
// Note: Matched 0 names
```

There are no instances of a library cell under /ret_i/ with instance name starting with add_2.

Example 5

find_design_names /ret_i/*_2? -ins -netlist -local

```
// Note: Matched 2 names
/ret_i/add_20
/ret_i/mul_22
```

Found 2 instances under /ret_i/.

Note

/ret_i/gt_68_2 did not match because the “?” in the wildcard expression requires another character after the “_2”.

Example 6

find_design_names */U5 -inst -design -hier

```
// Note: Matched 7 names
/tiny_i/U5
/ret_i/add_20/U5
/ret_i/mul_18/U5
/ret_i/mul_18/FS/U5
/ret_i/mul_19/U5
/ret_i/mul_19/FS/U5
/ret_i/mul_22/U5
```

Example 7

find_design_names ret_i/mul*/U5 -ins -des -local

```
// Note: Matched 3 names
/ret_i/mul_18/U5
/ret_i/mul_19/U5
/ret_i/mul_22/U5
```

Example 8

find_design_names ret_i/mul*/U5 -ins -design -hier

```
// Note: Matched 5 names
/ret_i/mul_18/U5
/ret_i/mul_18/FS/U5
/ret_i/mul_19/U5
/ret_i/mul_19/FS/U5
/ret_i/mul_22/U5
```

Example 9

find_design_names ret_i/mul_18/U5* -ins -library -hier

```
// Note: Matched 5 names
/ret_i/mul_18/U5
/ret_i/mul_18/U5/UD1
/ret_i/mul_18/U5/UD2
/ret_i/mul_18/U5/UD3
/ret_i/mul_18/U5/UD4
```

Example 10

find_design_names ret_i/mul*/U5/* -pin output -design -local

```
// Note: Matched 6 names
/ret_i/mul_18/U5/Q
/ret_i/mul_18/U5/QN
/ret_i/mul_19/U5/Q
/ret_i/mul_19/U5/QN
/ret_i/mul_22/U5/Q
/ret_i/mul_22/U5/QN
```

Example 11

find_design_names * -mod -list_references

```
// Note: Found 3 netlist modules
// Note: Instances of netlist module or_gate
/o1
/o2
// Note: Instances of netlist module pme_caam_RC_CG_MOD_335839

```

Example 12

find_design_names * -cell -list

```
// Note: Found 6 library cells
// Note: Instances of library cell HD45_SZ_MUX21X2
/mux
// Note: Instances of library cell HD45_SZ_LDLRX2
// Note: Instances of library cell HD45_SH_OR2X2
/o1/foo
/o2/foo
// Note: Instances of library cell HD45_SV_CNHLSX4
/RC_CG_HIER_INST3921/RC_CGIC_INST
// NOte: Instances of library cell HD45_SH_SDFPRQX4
/data_out_reg_0
/data_out_reg_1
/data_out_reg_2
/data_out_reg_3
/data_out_reg_4
/data_out_reg_5
/shadow
/non_scan
```

foreach_in_collection

Context: unspecified, all contexts

Mode: all modes

Usage

foreach_in_collection ***itr_var collection* {*body*}**

Description

Iterates over each element in a collection.

You cannot use the Tcl-supplied foreach command to iterate over collections because foreach operates on a Tcl list, and a collection is not a Tcl list but a pointer to an array of data on the C++ side. You can use the get_name_list command to convert the collection of objects into a Tcl list of object names, but you should avoid doing this if the collection is very large or if the object names are not unique, such as port names. For example, a port object is a specific port name on a specific module. Specifying just the name of the port does not indicate which module it belongs to.

You can nest the foreach_in_collection command within other control structures, including foreach_in_collection.

A collection remains in memory for as long as it is referenced by a Tcl variable. A collection is deleted once it is no longer referenced by any Tcl variable. If you make the mistake of using the Tcl command **foreach** to iterate on a collection, the command has the negative side effect of de-referencing the collection and may destroy it. Always use foreach_in_collection to iterate on the elements of a collection.

Arguments

- ***itr_var***

  A required string that specifies the name of a Tcl variable. During each iteration, itr_var holds a string pointer to a collection of exactly one object.

- ***collection***

  A required value that specifies a collection over which to iterate. It may be the content of a Tcl variable that points to a collection or the result of an introspection command that generates a collection. Note, just like the Tcl foreach command, a snapshot of the collection is taken before the first iteration. This means that even if the append_to_collection command is used to increase the size of the collection as part of the iterations, the foreach_in_collection command will not see the newly added elements. Example 3 shows how to collect new elements into a separate collection and use a Tcl while command to repeat the loop until the collection is truly empty.

- ***body***

  A required string that specifies a script to execute per iteration. The entire body must be enclosed within a set of braces.

Example 1

The following example connects a set of pins that has a special attribute called myAtt set to True to a net that has the same name as the pin. If not already present, the net is created. Note that the example assumes that all pins are scalar objects. Extra code would be needed to deal with bused pins and create the entire bused nets with one command. The is_bus and other built-in bus attributes are available to do this efficiently. Notice how the lindex command converts the return value of the get_attribute_value_list command into a string so that it can be used to construct the net name using ${parent}/${leaf}.

```
foreach_in_collection pin [get_pins -filter "myAtt"] {
        set leaf [lindex [get_attribute_value_list $pin -name leaf_name] 0]
        set parent [lindex [get_attribute_value_list $pin -name parent_instance] 0]
        if {[sizeof_collection [get_nets ${parent}/${leaf} -silent]] = 0} {
            create_net ${parent}/${leaf}
        }
        create_connections $pin ${parent}/${leaf}
}
```

Notice how filtering based on the value of an attribute is performed to reduce the size of the collection on which to iterate. The user could have chosen to loop on all pins and check inside the loop if the myAtt attribute is set to true, but this is very inefficient because filtering is done in C++ as opposed to looping in Tcl.

```
#inefficient use of looping. Best to filter collection before looping on
it as shown above.

foreach_in_collection pin [get_pins] {
        if {[get_attribute_value_list $pin -name myAtt]} {
            set leaf [lindex [get_attribute_value_list $pin -name leaf_name] 0]
            set parent [lindex [get_attribute_value_list $pin -name parent_instance] 0]
            if {[sizeof_collection [get_nets ${parent}/${leaf} -silent]] = 0} {
                create_net ${parent}/${leaf}
            }
            create_connections $pin ${parent}/${leaf}
        }
}
```

Example 2

The following example loops on a collection of pins and deletes them. The same pin object is added twice into the collection being looped on to illustrate the fact that obsolete objects are still looped on and that a -silent switch must be used so that they are ignored by the delete_pin command. Without the -silent option, an error would be generated the second time the pin object u1/P2 was looped on.

```
set my_pins [get_pins {u1/P2 u1/P*}]
puts "my_pins are [get_name_list $my_pins]"
foreach_in_collection pin $my_pins {
        delete_pin $pin -silent
}
```

```
my pins are u1/P2 u1/P1 u1/P2 u1/P3
```

Example 3

The following example shows how to iterate on a collection of objects until no objects are left to process. The procedure called “proc_that_returns_new_objects” is called on each object and may return new objects to process. The “append_to_collection col” command cannot be used to process the new objects because the foreach_in_collection command took a snapshot of “col” before the first iteration. Instead, the new objects are collected into a collection variable called “newCol” and it is assigned back to “col” after the foreach_in_collection command is done. The loop is repeated for as long as “newCol” is not empty after the foreach_in_collection command has completed.

```
set col [<start collection>]
while {[sizeof_collection $col] > 0} {
  set newCol {}
  foreach_in_collection obj $col {
    append_to_collection newCol [proc_that_returns_new_objects $obj]
  }
  set col $newCol
}
```

get_attribute_list

Context: unspecified, all contexts

Mode: all modes

Usage

Usage 1: List attributes specified on a group of objects

get_attribute_list ***obj_spec*** [-predefined | -user_defined] [-silent]

Usage 2: List attributes registered for a groups of object types

get_attribute_list **-object_types *type_list*** [-predefined | -user_defined] [-silent]

Usage 3: List all registered attributes

get_attribute_list [-predefined | -user_defined] [-silent]

Description

Returns an alphabetically sorted Tcl list of attribute names.

Usage 1: Returns the attributes set on any object found in *obj_spec*. The attributes on an object inherited from an associated object are reported. For example, an attribute registered for the module object type and set on a given module object are reported in the list of attributes for the instances of that module. By default, attributes that have not been set on the objects are not listed unless the attribute was registered with the -show_default option.

If an object in *obj_spec* does not exist, an error message displays unless the -silent switch is specified.

Usage 2: Returns the attributes registered for all specified object types. These do not include the inherited attributes from one object type to another such as the module attribute inherited by the associated instances.

Usage 3: Returns all registered attributes

In all three usages, only predefined attributes are returned when the -predefined option is specified. Only user-defined attributes are returned when the -user_defined option is specified.

Arguments

- ***obj_spec***

  A required value used in Usage 1 that specifies an object name, a Tcl list of object names, or a collection of objects.

- **-object_types *type_list***

  A required switch and value pair used in Usage 2 that enumerates the object types for which the attribute list is requested. The currently supported object types are module, port, instance, pin, and net. The list of supported object types will be augmented in successive releases and eventually all object types with be available for introspection.

- -predefined | -user_defined

  An optional switch that constrains the returned list to only pre-defined attribute names or only user-defined attribute names. If this argument is not specified, by default no constraints are applied and both pre-defined and user-defined attributes are returned.

- -silent

  An optional switch that specifies to suppress error messages if there are objects in the *object_spec* that do not exist.

Example 1

The following example lists the attributes set on three pins:

get_attribute_list {tiny1_3/d1 tiny1_3/d2 tiny1_3/d3}

```
base_name direction has_functional_source is_hard_module is_valid
leaf_name library_name master_module_name module_name name object_type
parent_instance parent_is_hard_module tie_value
```

Example 2

The following example shows the impact of using the -show_default switch, when registering an attribute, on the get_attribute_list command:

register_attribute -name a1 -value_type boolean -object_types pin
get_attribute_list {u1/pin1 u1/pin2} -user_defined

```
{}
```

register_attribute -name a2 -value_type boolean -object_types pins -show_default
get_attribute_list {u1/pin1 u1/pin2} -user_defined

```
a2
```

set_attribute_value u1/pin1 -name a1

```
{u1/pin1}
```

get_attribute_list {u1/pin1 u1/pin2} -user_defined

```
a1 a2
```

get_attribute_option

Context: unspecified, all contexts

Mode: all modes

Usage

get_attribute_option **-name** ***attribute_name*** **-object_type** ***type_name***
{[-export_during_write {auto | off | on}] |
[-preserve_boundary_in_flat_model] |
[-applies_to_child_instances] |
[-display_in_gui **{**off **|** on**}] |**
[-gui_marking_index *marking_index*]}

Description

Retrieves the current setting of an attribute's option.

The get_attribute_option command returns a string with the option settings of the specified attribute. These options can be modified after the attribute has been registered using the set_attribute_options command.

Arguments

- **-name** ***attribute_name***

  A required switch and value pair that specifies the name of the attribute whose option values are to be returned.

- **-object_type** ***obj_type***

  A required switch and value pair that specifies the object type whose attribute option settings are to be returned.

- -export_during_write

  An optional switch that retrieves the current value of the export_during_write option for the specified attribute name on the specified object type. For more information on the -export_during_write switch, see the set_attribute_options command.

- -preserve_boundary_in_flat_model

  An optional switch that retrieves the current value of the -preserve_boundary_in_flat_model option for the specified attribute name on the specified object type. For more information on the -preserve_boundary_in_flat_model switch, see the set_attribute_options command.

- -applies_to_child_instances

  An optional switch that retrieves the current value of -applies_to_child_instances for the specified attribute name on the specified object type. For more information on the -applies_to_child_instances switch, see the set_attribute_options command.

- -display_in_gui

  An optional switch that retrieves the current value of the -display_in_gui option for the specified attribute name on the specified object type. For more information on the -display_in_gui switch, see the set_attribute_options command.

- -gui_marking_index

  An optional switch that retrieves the current value of the -gui_marking_index for the specified attribute name on the specified object type. For more information on the -gui_marking_index switch, see the set_attribute_options command.

Example

The following example retrieves the -applies_to_child_instances setting for the attribute named my_power_domain which is registered for the instance object type:

```
get_attribute_option -name my_power_domain -object_type instance
        -applies_to_child_instances
```

```
on
```

get_attribute_value_list

Context: unspecified, all contexts

Mode: all modes

Usage

get_attribute_value_list ***object_spec*** **-name** ***attribute_name*** [-silent]

Description

Retrieves the value of an attribute on the specified design objects.

Like all other Tessent commands ending with an _list suffix, this command returns a list with all the values set for the attribute on each of the objects in object_spec.

If an object in object_spec does not exist, or if the attribute specified by attribute_name does not exist on the design object, an error message displays unless the -silent switch is specified.

Arguments

- ***object_spec***

  A required value that specifies an object name, a Tcl list of object names or a collection of objects.

- **-name** ***attribute_name***

  A required switch and string pair that specify the name of the attribute whose value is to be returned.

- -silent

  An optional switch that specifies to suppress error messages if an object in object_spec does not exist, or if the attribute specified by attribute_name does not exist for a given design object.

Example 1

The following example returns the value of parent_instance value for pins. The get_attribute_value_list command returns a Tcl list of values even if there is only one object in obj_spec. Use lindex as shown below to convert any one element list into a string that you can then concatenate with other strings to create object names. The 0 argument to the lindex command below takes the first (and only) element of the list.

get_attribute_value_list u1/u5/u8/ABC -name parent_instance

```
u1/u5
```

get_attribute_value_list u1/DEF -name parent_instance

```
{}
```

lindex [get_attribute_value_list u1/DEF -name parent_instance] 0

Example 2

The following example retrieves values for the attribute named “is_hard_module” on the listed modules.

get_attribute_value_list {alu mux2 rom3} -name is_hard_module

```
false true false
```

set myList {mux2 alu}
get_attribute_value_list $myList -name is_hard_module

```
true false
```

get_cdp_test_list

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

get_cdp_test_list

Description

Returns a Tcl list of tests currently available in the CDP.

Example

The following example shows how you can use this command to return a Tcl list of the current tests within the CDP.

```
foreach test [get_cdp_test_list] {
        execute_cdp_test $test
}
```

```
taptest membist1 membist2 logicbist1 logicbist2
```

get_clock_list

Context: all contexts

Mode: setup, analysis

Prerequisites: The current design must be set.

Usage

get_clock_list

Description

Returns a list of all clocks specified with the add_clocks command.

Arguments

None.

Example

The following example adds two clocks to the clock list and then returns a list of the clocks:

```
add_clocks 1 clk1
add_clocks 0 clk0
get_clock_list
clk1 clk0
```

Related Commands

get_clock_option

Context: all contexts

Mode: setup, analysis

Prerequisites: The current design must be set.

Usage

get_clock_option ***pin_pathname*** { -is_sync | -off_state | -free_running
| -period [-timeplate *timeplate*] [-time_unit { ps | ns | us | ms | s }]
| -divider | -always_capture | -internal }

Description

Returns the setting of an option specified with the add_clocks command.

The get_clock_option command returns the setting of a single option type for one or more defined clocks. You can use the get_clock_list command to gather the list of defined clocks.

Arguments

- ***pin_pathname***

  A required value that specifies one or more pin names previously defined as a clock with the add_clocks command.

  The get_clock_option command requires one of the following switches:

- -is_sync

  An optional switch that returns a ‘1’ if driven from a timeplate and a ‘0’ if specified by the “add_clocks -period” command.

- -off_state

  An optional switch that returns the value of the off-state (1 or 0).

- -free_running

  An optional switch that returns a ‘1’ if the pin_pathname is a free-running clock, and returns a ‘0’ if not.

- -period [-timeplate *timeplate*] [-time_unit { ps | ns | us | ms | s }]

  An optional switch that returns the clock period if previously specified with the “add_clocks -period” command. Otherwise, you must use the -timeplate switch to identify the timeplate that drives the clock. You can use the -time_unit switch if you want to return the clock period in units other than nanoseconds.

- -divider

  An optional switch that returns an integer value that specifies the divider of a free-running clock, which you can set with the “add_clocks -divider” command. The switch returns an integer value of ‘1’ for undivided or non-free-running clocks.

- -always_capture

  An optional switch that returns a ‘1’ if the pin is an always-capture clock, and returns a ‘0’ if not.

- -internal

  An optional switch that returns a ‘1’ if the clock was previously specified with the “add_clocks -internal” switch, and returns a ‘0’ if not.

Example

The following example adds two clocks to the clock list, reports on the clocks, then shows two ways of using the get_clock_option command:

SETUP> **add_clocks 1 I8**
SETUP> **add_clocks 0 I6 -free_running -period 5**
SETUP> **report_clocks**

```
User-defined Clocks (2):
 ---------  ------------  --------  ----  ----------------
 Off State   Constraints  Internal  Name  Other Properties
 ---------  ------------  --------  ----  ----------------
     1                       No     I8
     0      Asynchronous     No     I6    (period:5.00ns)
```

SETUP> **get_clock_option {I6 I8} -off_state**
0 1

SETUP> **get_clock_option [get_clock_list] -free_running**
1 0

get_common_parent_instance

Context: all contexts

Mode: all modes

Usage

get_common_parent_instance ***object_spec***

Description

Returns the common ancestor of all instances, pins, or nets found in object_spec.

You can use this command during dft insertion when you want to place a driving gate at the common ancestor of all its fanouts.

Arguments

- ***object_spec***

  A required value that specifies an object name, a Tcl list of object names, or a collection of objects to find their common ancestor.

Example

The following example finds the common ancestor of all pins having the attribute myAtt set to true. The name of the returned instance object is then used to instantiate a driver cell. Notice how quotes are used around the concatenation of ${parent_name} and /myGate to make sure that any white spaces that may exist in ${parent_name} (when it contains escaped identifiers) are preserved.

```
set parent [get_common_parent_instance [get_pins -filter myAtt]]
set parent_name [get_single_name $parent]
set driver [create_instance “${parent_name}/myGate” -of_module MyMod]
```

get_config_elements

Context: unspecified, dft, patterns

Mode: all modes

Usage

get_config_elements [*name_patterns*] [-hierarchical] [-in_wrappers *wrapper_object_spec*]
[-partition *partition*] [-count] [-type *type*] [-filter *filter*]
[-regexp] [-nocase] [-silent]

Description

Returns a collection of configuration elements or a count of configuration elements when the -count option is used.

When no name_patterns is specified, then all elements are returned unless the -in_wrapper option is specified, in which case only the elements in the specified wrappers are returned. When using one or many name_patterns, only the elements whose name matches one of the name_patterns are returned.

Arguments

- *name_patterns*

  An optional string that specifies one name pattern or a Tcl list of name patterns to search. The name patterns are automatically decomposed into a series of anchored leaf name patterns using the / as a separator. The name identifiers are always matches ignoring case. The ids found inside the parentheses are matched taking into account case unless the -nocase option is used. The comma has special meaning inside the parentheses and is used to split the patterns and match each id independently. A leaf pattern that does not include a set of parentheses matches all elements matching the leaf name irrespective of whether it has ids or not. See the examples below for a complete illustration of the matching method.

  When the -in_wrapper option is specified, the name_patterns are described relative to the specified wrappers, When the -hierarchical option is specified, the name_patterns are matched recursively against all elements below the specified wrappers.

- -hierarchical

  An optional string that specifies that the name_patterns are matched recursively against all elements below the specified wrappers.

- -in_wrapper *wrapper_object_spec*

  An option value pair that specifies that the configuration elements are to be searched inside specific wrappers. When the -in_wrapper option specified, the name_patterns are searched relative to the specified wrappers. The wrapper_object_spec can be the complete names of wrappers relative to the root of the partition or a collection containing one or many wrapper elements as returned by get_config_elements or “get_config_value -object”. When specifying the names of the wrapper, you can use the -partition option to specify in which partition the wrappers exist.

- -partition *partition_name*

  An optional option value pair that specifies the partition from which the configuration element is to be obtained. When using the -in_wrapper option, the -partition option can only be specified if the wrapper_object_spec is the name of a wrapper. When the wrapper_object_spec is a collection containing wrapper objects, the -partition option cannot be specified because a specific partition is already associated to the configuration objects. All configuration data you normally interact with is in the default partition, so you typically never need to specify the -partition option.

  The tool currently defines two partitions: the default partition in which all user specifications are stored, and the tcd partition which is a read-only partition in which the read_core_descriptions commands stores the data contained inside the Core(module_name) wrapper. The default partition contains the definition of DftSpecification, and DefaultsSpecification/DftSpecification wrappers.

- -count

  An optional Boolean option that specifies to return the number of elements matched as opposed to the elements themselves.

- -type wrapper | data_wrapper | csv_wrapper | property

  An optional option value pair that specifies to limit the search to a specific configuration element type. When the -type option is omitted, all types are considered in the matching.

- -filter attribute_equation

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the configuration element types being filtered. See section "Attribute Filtering Equation Syntax" for more details on filtering attribute equation format. The =~ and !~ matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument as a regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when matching the Ids of wrapper and repeatable properties. The wrapper and property names are always matched ignoring casing.

- -silent

  An optional option that suppress the warning that is normally generated when no configuration element matched the name_patterns.

Example

The following example operates on the following configuration data:

```
tmp(1) {
  ABC (Def,2) {
    prop1 : 1;
    Prop2 : 2;
  }
  abc(def,1) {
  }
  abcdef {
  }

}
```

Case 1

This matches all wrappers with a leaf name starting with abc inside wrapper tmp(1) independent of whether it has an id. The matching is case-insensitive because only the id matching is case-sensitive.

```
> get_config_element abc -in tmp(1)
{/tmp(1)/ABC(Def,2) /tmp(1)/abc(def,1)}
```

Case 2

This matches the wrappers with the first id equal to Def. Notice that it does not match abc(def,1) as ids are matched considering casing unless the -nocase option is used.

```
> get_config_elements *(Def,*) -in tmp(1)
{/tmp(1)/ABC(Def,2)}

> get_config_elements *(Def,*) -in tmp(1) -nocase
{/tmp(1)/ABC(Def,2) /tmp(1)/abc(def,1)}
```

Case 3

This matches elements below the top-level wrapper starting with a*.

```
> get_config_element */a*
{/tmp(1)/ABC(Def,2) /tmp(1)/abc(def,1) /tmp(1)/abcdef}}
```

Case 4

This matches elements below the top-level wrapper starting with a* and having two ids.

```
> get_config_element */a*(*,*)
{/tmp(1)/ABC(Def,2) /tmp(1)/abc(def,1)}}
```

Case 5

This matches elements starting with ‘p’ anywhere inside tmp(1).

```
> get_config_element p* -in tmp(1)  -hierarchical
{/tmp(1)/ABC(DeF,2)/prop1 /tmp(1)/ABC(DeF,2)/Prop2}
```

Case 6

This matches elements starting with ‘p’ anywhere inside tmp(1) and returns the amount of elements that matched instead of the elements themselves.

```
> get_config_element p* -in tmp(1)  -hierarchical -count
2
```

Related Commands

add_config_element

get_config_value

get_config_messages

Context: unspecified, dft, patterns

Mode: all modes

Usage

get_config_messages *config_object_spec*
[-string | {-objects [-hierarchical]}]
[-all | {[-error] [-warning] [-info]]

Description

Returns a list of message strings attached to a configuration element.

By default, all message types are returned unless the -error, -warning, and/or -info options are specified. If the -objects option is specified, the command returns the configuration element if it has messages of the specified type.

Arguments

- *config_object_spec*

  A required value that specifies the name of a configuration element or a collection containing one configuration element.

- -string

  An optional Boolean option that specifies that the command is to return the messages formatted into strings exactly as they are shown with the report_config_messages command. The entries start with E#), W#) and I#) based on the type of the message and # is incremented from 0 independently for each type.

  The use of -string is mutually exclusive with the -objects option, When either is specified, -string is assumed.

- -objects

  An optional Boolean option that specifies to return a collection of configuration elements having at least one message of the specified type.

- -hierarchical

  An optional Boolean option that specifies that the config_object_spec is a wrapper and that the command should return all elements below the specified wrapper having at least one configuration message for the specified types. This option is only allowed in combination with the -objects option

- -all

  An optional Boolean option that specifies that all messages types are to be returned. The use of the -all option is mutually exclusive with the specification of the -error, -warning and -info options. When none of the four options is specified, -all is assumed.

- -error

  An optional Boolean option that specifies that the messages returned are of type error. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

- -warning

  An optional Boolean option that specifies that the messages returned are of type warning. The use of the -error option is mutually exclusive with the specification of the -all, -warning, and -info options. When none of the -error, -warning, and -info options is specified, -all is assumed.

- -info

  An optional Boolean option that specifies that the messages returned are of type info. The use of the -error option is mutually exclusive with the specification of the -all, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

Example

The following example adds an error message to the property rtl_extension inside DftSpecification(mydesign,rtl). The get_config_messages is then used to get the message string list on the property. The command “get_config_messages -objects -hierarchical” is also used to get a collection of all elements below DftSpecification(mydesign,rtl) with an error message.

```
> set_context dft -rtl
> set spec [add_config_el DftSpecification(mydesign,rtl)]
> add_config_message "this is an error string \non two lines" \
       -config_element [get_config_el rtl_extension -in $spec] \
       -error -display
//  Error: /DftSpecification(mydesign,rtl)/rtl_extension
//         this is an error string
//         on two lines
> get_config_messages [get_config_el rtl_extension -in $spec]
E0) this is an error string
    on two lines
> get_config_messages $spec -objects -hier
{/DftSpecification(mydesign,rtl)/rtl_extension}
```

Related Commands

add_config_message
delete_config_messages
report_config_messages

get_config_selected_nodes

Context: dft, patterns

Mode: all modes

Usage

get_config_selected_nodes

Description

Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data window.

Arguments

None

Example

The following example shows the result of the command when two nodes are selected in the Configuration Data window as shown in Figure 7-11. You can select more than one element by pressing the Shift or Control key while selecting the second element.

```
> get_config_select_node
{/DftSpecification(mydesign,rtl)/MemoryBist/Controller(1)
/DftSpecification(mydesign,rtl)/MemoryBist/Controller(2)}
```

Figure 7-11. Selecting Two Nodes in the Configuration Tree

Related Commands

get_config_value

Context: unspecified, all contexts

Mode: all modes

Usage

get_config_value *config_object* [-in_wrapper *wrapper_object_or_name*]
[-time_unit {s | ms | us | ns | ps | fs}]
[-number_format {int | bin | hex}]
[-reference_name | -reference_object | -parent_name | -parent_object | -root_name | -type | -name | -id *id* | -value_id *value_id* | -is_specified | -id_count | -value_count | -exists | -root_name | -root_object | -leaf_name | -base_name |-meta_name | -meta_object | -meta_id | -partition_name]
[-default_value] [-tolower | -toupper] [-file_name] [-object]
[-partition *partition*] [-silent]

| *id_name* | all} | -value_id {*<position>* | *value_name* | all} |*value_name* | all} |

Description

Returns different values associated with a configuration element based on the specified option.

Figure 7-12 below illustrates some of those values.

Figure 7-12. Various Components of a Configuration Element

Arguments

- ***config_spec***

  A required value that specifies the name of a configuration element or a collection containing one configuration element. When config_spec is a collection, the -in_wrapper and -partition options cannot be used because the object contains all of the information about the configuration element. In order to use the -in_wrapper option, the config_spec value must be a name and the name must be relative to the specified wrapper element. You can use a positional id for any level of hierarchy. You can also replace the id of a leaf name by the position. For example, the path “tmp(1)/<0>/wrp<1>” means “tmp(1)/wrp(abc)/wrp(def)” if “wrp(abc)” is the first element found inside “tmp(1)” and “wrp(def)” is the second instance of a wrapper with a base name of “wrp” inside “tmp(1)/wrp(abc)”.

- -in_wrapper *wrapper_object_spec*

  An optional option value pair that is used to specify the parent wrapper in which the configuration element exists. The wrapper_object_spec value is the name of a wrapper or a collection containing a wrapper element. The name in the config_element_name is relative to the specified parent wrapper.

- -time_unit s | ms | us | ns | ps | fs | as_is

  An optional Boolean option that can be used when the command is returning a Value time property value; it is ignored otherwise. When specified or defaulted to as_is, the time value is returned unmodified with the unit string specified if it existed in the value of the configuration element. When specified to a value other than as_is, the time value is converted into a real number formatted to the specified units. The unit string is also dropped.

- -number_format int | bin | hex | as_is

  An option value pair that can be used when the command is returning a Value binary property or hexadecimal value. It is ignored otherwise. When specified or defaulted to as_is, the value is returned unmodified with the format if it existed in the value of the configuration element. When specified to a value other than as_is, the binary or hexadecimal value is converted into the specified format.

- -reference_name

  An optional Boolean option that specifies that the data requested is the name of the referenced metadata element. If the metadata is not a Wrapper reference property, this returns a null string.

- -reference_object

  An optional Boolean option that specifies that the data requested is a collection containing the referenced metadata element. If the metadata is not a Wrapper reference property, this returns an empty collection.

- -parent_name

  An optional Boolean option that specifies that the data requested is the name of the wrapper in which the configuration element exists. If the element is a root wrapper, the string / is returned.

- -parent_object

  An optional Boolean option that specifies that the data requested is a collection containing the wrapper in which the configuration element exists. If the element is a root wrapper inside a given partition, a collection containing the partition in which the root wrapper exists is returned.

- -type

  An optional Boolean option that specifies that the data requested is the type of the configuration element. The type is either wrapper, data_wrapper, csv_wrapper, property,

repeatable_property, data_element, or csv_element. Table 7-9 explains each type in more details.

Table 7-9. Types of Configuration Elements

Type	Description
wrapper	Type returned for a Wrapper used to groups other wrappers and properties.
data_wrapper	Type returned for a DataWrapper used to group data_row elements.
csv_wrapper	Type returned for a CsvWrapper used to group csv_row elements.
property	Type returned for a Property.
repeatable_property	Type returned for a RepeatableProperty property.
data_row	Type returned for elements found inside a DataWrapper.
csv_row	Type returned for elements found inside a CsvWrapper.

- -name

  An optional Boolean option that specifies that the data requested is the name of the configuration element. As shown in Figure 7-12, the name is the complete name including all hierarchical levels. If at any level in the hierarchy, the leaf_name is not unique, the leaf_name is replaced by a positional index so as to have a unique name for each element. For example, if there are two instances of the same wrapper called “port(abc)” inside the same parent wrapper called “ports”, the name would be reported as “/Ports/Port(<2>)” assuming it is the third element inside “/ports”.

- -id *position* | *id_name* | all

  An optional option value pair that specifies that the data requested is the id of a wrapper or of a repeatable property. When using -id all, the command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non repeatable Id declared for it. In this case the value is returned as a tcl string which is the case for most wrappers and repeatable properties you will introspect.

  When you have configuration elements with more than one Id, you can query one id at a time using either its position or when it has metadata, the id of the ID wrapper that declares the id. A position is represented with an integer surrounded by <>. For example, <0> is the first value, <1> is the second, and so on. In such a case, the id is returned as a string except when using the id of a repeatable id in which case a well-formatted Tcl list is returned.

- -value_id *position* | *value_name* | all

  An optional option value pair that specifies that the data requested is the value of a property, repeatable property, or of a row inside a Data or CSV wrapper. If none of the options listed between -value_count and -reference_object inclusively are specified, “-value_id all” is assumed.

When using “-value_id all”, the command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable value declared for it. In this case, the value is returned as a Tcl string which is the case for most properties you introspect.

When you have configuration elements with more than one elements, you can query one value at a time using either its position or, if it has metadata, the id of the Value wrapper that declares the value. A position is represented with an integer surrounded by <>. For example, <0> is the first value, <1> is the second, and so on. In such a case, the value is returned as a string except when using the id of a repeatable Value in which case a well-formatted Tcl list is returned.

- -is_specified

  An optional Boolean option that specifies that the data requested is a Boolean value that is 1 when the configuration element is specified and 0 when it is not. Remember that singular wrappers and properties exist as soon as their parent wrapper exists and regardless of whether the singular wrapper or property is specified. The parent wrapper must exist before you can query if one of its element is specified. Unspecified elements are not included in the output file when using the write_config_data or the report_config_data commands unless the -show_unspecified option is used.

- -id_count

  An optional Boolean option that specifies that the data requested is the number of ids specified for the wrapper of repeatable property. A value of 0 is returned for configuration objects that do not have ids like a wrapper declared without any Id wrapper or a property.

- -value_count

  An optional Boolean option that specifies that the data requested is the number of values specified for the property, the Data or CSV wrapper row. A value of 0 is returned for configuration objects that do not have values like a wrapper. Implicit Boolean properties still report one value because the true or false value is implicit but still present.

- -exists

  An optional Boolean option that specifies that the data requested is a Boolean value that is 1 when the configuration element exists and 0 when it does not. Remember that singular wrappers and properties exist as soon as their parent wrapper exists and whether the singular wrapper or property is specified or not. You use the -is_specified option to know if such elements are specified or not.

- -root_name

  An optional Boolean option that specifies that the data requested is the name of the root wrapper in which the configuration element exists. If the element is a root wrapper, its name is returned.

- -root_object

  An optional Boolean option that specifies that the data requested is a collection containing a root wrapper in which the configuration element exists. If the element is a root wrapper, it is returned in the collection.

- -leaf_name

  An optional Boolean option that specifies that the data requested is the leaf name of the configuration element. As shown in Figure 7-12, the leaf name is the last level of hierarchy including the base_name and the ids when they exist.

- -base_name

  An optional Boolean option that specifies that the data requested is the base name of the configuration element. As shown in Figure 7-12, the base name is the last level of hierarchy excluding the ids when they exist.

- -meta_name

  An optional Boolean option that specifies that the data requested is the name of the Wrapper wrapper used to define the configuration element. The name is constructed assuming the metadata data was declared with no Wrapper reference property to shared declaration. The -reference_name option is used to get the name of the element referenced.

- -meta_object

  An optional Boolean option that specifies that the data requested is a collection containing the Wrapper wrapper used to define the configuration element. The object is the metadata data element as if it was declared with no Wrapper reference property to shared object. The reference_object option is used to get the referenced object.

- -meta_id

  An optional Boolean option that specifies that the data requested is a unique integer corresponding to the Wrapper wrapper used to define the configuration element. The meta_id of an element declared with the Wrapper reference property is the meta_id of the referenced element.

- -partition_name

  An optional Boolean option that specifies that the data requested is the name of the partition in which the configuration element exists. Table 7-10 shows the returned value based on which partition the configuration element exists in.

- -default_value

  An optional option value pair that specifies that the data requested is the default value of a property. The command returns a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable value declared for it. In this case, the default_value is returned as a Tcl string which is the case for most properties you introspect.

  You can use the -value_id option in combination with the -default_value to obtain the default value of a specific value. When requesting the default value of a single value, the return value is always a well-formatted Tcl string.

- -tolower

  An optional Boolean option that can be used when the command is returning a string. It is ignored otherwise. All upper case letters are converted to lower case.

- -toupper

  An optional Boolean option that can be used when the command is returning a string. It is ignored otherwise. All lower case letters are converted to upper case.

- -file_name

  An optional Boolean option that specifies that the data requested is the file name from which the configuration element was read. It returns null if the configuration element was not read from a file using read_config_data but instead it was created in memory using add_config_element. The file_name value is updated to point to the output file name as soon as it is written out using the write_config_data command.

- -object

  An optional Boolean option that specifies that the data requested is a collection containing the configuration element just like add_config_element returns when adding an element.

- -partition *partition_name*

  An optional option value pair that is used to specify the partition in which the configuration element exists. When the option is unspecified, the default partition is used which is where all specifications (DftSpecification and DefaultsSpecification/DftSpecification) are located. You can access the Core wrappers comprising the Tessent Core Description (TCD) file syntax in the tcd partition. Using the partition names meta: and meta:tcd allows you to access the metadata configuration elements that define the default and tcd partitions. Table 7-10 summarizes the available partition names.

Table 7-10. Available Partitions for Introspection

Partition name	Configuration data contained
	When the -partition option is unspecified, the Default partition is accessed which is where the DftSpecification and DefaultsSpecification/DftSpecification configuration data is located.
tcd	When the -partition option is specified with the tcd value, the Core wrappers comprising the Tessent Core Description file syntax is accessed.
meta	When the -partition option is specified with the meta value, the metadata configuration data defining the allowed syntax of the DftSpecification and DefaultsSpecification/DftSpecification is accessed.
meta:tcd	When the -partition option is specified with the meta:tcd value, the metadata configuration data defining the allowed syntax of the Core wrappers is accessed.

Example

This example shows usage of the get_config_value command with a wide variety of its options exercised. You can see the syntax of the configuration data at the top and the specific configuration data being introspected just after. At the bottom of the example, you can see the metadata defining the syntax.

```
//  command: set_context dft -rtl
//  command: report_config_syntax SingularWrapper
SingularWrapper {
  WrapperWithRepeatableId(<name*>) {
    WrapperWithRepeatableId(<name*>) {
      // Same as /SingularWrapper/WrapperWithRepeatableId
    }
    time_property    : <time>        ; // default: 3.5ns
    integer_property : <integer>     ; // default: 3
    binary_property  : <binary>      ; // default: 3'b0
    string_property  : <string>, ... ;
    CsvWrapper(<module_name>,<design_id>) {
      <value>,...;
    }
    DataWrapper_with_no_value {
      <port> ; // repeatable
    }
    DataWrapper_value {
      <port> : <period> ; // repeatable
    }
  }
}
//  command: read_config_data ./data/cfg
//  command: report_config_data SingularWrapper

SingularWrapper {
  WrapperWithRepeatableId(a,b c) {
    WrapperWithRepeatableId(abc) {
      time_property : 4.5ns;
      integer_property : 6;
      binary_property : 4'b110;
      string_property : this is a string;
      CsvWrapper(moda,id1) {
        a;
        b, c;
        d, e f, g;
      }
      DataWrapper_with_no_value {
        a string ;
        1;
      }
      DataWrapper_value {
        clka : 4ns;
        clkb : 6.7ms;
        clkc : 4;
      }
    }
  }
```

```
}
> set wrp [get_config_el WrapperWithRepeatableId(abc) -hier]
```

Case 1:

Get the value of a property where the type is time:

```
> puts [get_config_value time_property -in $wrp]
4.5ns
```

Case 2:

Get the time value in milliseconds with units removed:

```
> puts [get_config_value time_property -in $wrp -time_unit ms]
4.5e-06
```

Case 3:

Get the time value in nanoseconds with units removed:

```
> puts [get_config_value time_property -in $wrp -time_unit ns]
4.5
```

Case 4:

Get the value of a property where the type is integer:

```
> puts [get_config_value integer_property -in $wrp]
6
```

Case 5:

Get the value of a property where the type is binary:

```
> puts [get_config_value binary_property -in $wrp]
4'b110
```

Case 6:

Get the value of a property with a binary value converted in hexadecimal:

```
> puts [get_config_value binary_property -in $wrp -number_format hex]
4'h6
```

Case 7:

Get the value of a property with a binary value converted to integer:

```
> puts [get_config_value binary_property -in $wrp -number_format int]
6
```

Case 8:

Get the value of a property where the type is sting:

```
> puts [get_config_value string_property -in $wrp]
this is a string
```

Case 9:

Get the leaf_name of a wrapper:

```
> puts [get_config_value $wrp -leaf_name]
WrapperWithRepeatableId(abc)
```

Case 10:

Get the base_name of a wrapper:

```
> puts [get_config_value $wrp -base_name]
WrapperWithRepeatableId
```

Case 11:

Get a cvs wrapper object and return the number of rows in csv wrapper:

```
> set csv [get_config_value CsvWrapper(moda,id1) -in $wrp -object]
> puts [get_config_element -in $csv -count]
3
```

Case 12:

Get the values of CSV rows:

```
> puts [get_config_value CsvWrapper(moda,id1)/<0> -in $wrp]
a
> puts [get_config_value CsvWrapper(moda,id1)/<1> -in $wrp]
b c
> puts [get_config_value CsvWrapper(moda,id1)/<2> -in $wrp]
d {e f} g
```

Case 13:

Get the number of values in a row:

```
> puts [get_config_value CsvWrapper(moda,id1)/<2> -in $wrp -value_count]
3
```

Case 14:

Get specific value of a CSV row:

```
> puts [get_config_value CsvWrapper(moda,id1)/<2> -in $wrp -value_id <1>]
e f
```

Above is equivalent to

```
> puts [lindex [get_config_value CsvWrapper(moda,id1)/<2> -in $wrp] 1]
e f
```

Case 15:

Get the number of the id for a wrapper element:

```
> puts [get_config_value -id_count \
          SingularWrapper/WrapperWithRepeatableId<0>]
2
```

Case 16:

Get the leaf_name of a wrapper element:

```
> puts [get_config_value -leaf_name $wrp]
WrapperWithRepeatableId(abc)
```

Case 17:

Get the name of a wrapper element:

```
> puts [get_config_value $wrp]
SingularWrapper/WrapperWithRepeatableId(abc)
```

Case 18:

Get the base_name of a wrapper element:

```
> puts [get_config_value -base_name $wrp]
WrapperWithRepeatableId
```

Case 19:

Get the parent_name of a wrapper element:

```
> puts [get_config_value -parent_name $wrp]
/SingularWrapper/WrapperWithRepeatableId(a,b c)
```

Case 20:

Get the parent_object of a wrapper element:

```
> puts [get_single_name [get_config_value -parent_object $wrp]]
/SingularWrapper/WrapperWithRepeatableId(a,b c)
```

Case 21:

Get the root_name of a wrapper element:

```
> puts [get_config_value -root_name $wrp]
/SingularWrapper
```

Case 22:

Get the root_object of a wrapper element:

```
> puts [get_single_name [get_config_value -root_object $wrp]]
/SingularWrapper
```

Case 23:

Get the file_name of a wrapper element:

```
> puts [get_config_value -file_name $wrp]
/home/abc/data/ex.cfg
```

Case 24:

Gets the meta_name of a wrapper element:

```
> puts [get_config_value -meta_name $wrp]
/Wrapper(SingularWrapper)/Wrapper(WrapperWithRepeatableId)
```

Case 25:

Gets the ref_name of a metadata element. Returns null when the element is not referencing another one:

```
> puts [get_conf_value \
       SingularWrapper/WrapperWithRepeatableId/WrapperWithRepeatableId \
       -part meta -ref_name]
/Wrapper(SingularWrapper)/Wrapper(WrapperWithRepeatableId)
> puts [get_conf_value SingularWrapper/WrapperWithRepeatableId  \
       -part meta -ref_name]
```

Case 26:

Uses -lolower and -toupper options to convert the returned string in lower case or upper case:

```
> puts [get_config_value -base_name $wrp]
WrapperWithRepeatableId
> puts [get_config_value -base_name $wrp -toupper]
WRAPPERWITHREPEATABLEID
> puts [get_config_value -base_name $wrp -tolower]
wrapperwithrepeatableid
```

Case 27:

Reports the metadata that defines the syntax being introspected:

```
> report_config_data SingularWrapper -partition meta
Wrapper(SingularWrapper) {
  Repeatable : single;
  Wrapper(WrapperWithRepeatableId) {
    id(name*) {
      type : string;
    }
    Reference = /SingularWrapper/WrapperWithRepeatableId;
    Property(time_property) {
      Value(time) {
        type : time;
        DefaultValue : 3.5ns;
      }
    }
    Property(integer_property) {
      Value(integer) {
        type : int;
        DefaultValue : 3;
      }
    }
    Property(binary_property) {
      Value(binary) {
        type : binary;
        DefaultValue : 3'b0;
      }
    }
    Property(string_property) {
      Value(string*) {
        type : string;
        DefaultValue : "";
      }
    }
    CSVWrapper(CsvWrapper) {
      Repeatable : on;
      id(module_name) {
        Type : String;
      }
      id(design_id) {
        Type : String;
        IgnoreCase : On;
      }
    }
    DataWrapper(DataWrapper_with_no_value) {
      RowIdElement(port) {
```

```
            Type : String;
            repeatable : on;
          }
        }
        DataWrapper(DataWrapper_value) {
          RowIdElement(port) {
            Type : String;
            repeatable : on;
          }
          Value(period) {
            Type : time;
          }
        }
      }
    }
```

Related Commands

set_config_value

add_config_element

get_context

Context: unspecified, all contexts

Mode: all modes

Usage

get_context [-scan | -ijtag | -scan_diagnosis | -extraction | -atpg | -edt | -logic_bist | -rtl | -no_rtl] -design_identifier

Description

Introspects the current context.

When specified without an option, this command returns dft or patterns. When specified with one of the available options, this command returns 1 if the specified sub-context is active.

Arguments

- -scan

  An option that returns 1 when set_context -scan is specified.

- -ijtag

  An option that returns 1 when set_context -ijtag is specified.

- -scan_diagnosis

  An option that returns 1 when set_context -scan_diagnosis is specified.

- -extraction

  An option that returns 1 when set_context -ijtag is specified. When set_current_design is executed, the extraction sub-context is set to 1 if the ICL module for the current design has not already been loaded; in this case, it will be extracted when set_system_mode analysis is executed.

- -atpg

  An option that returns 1 when set_context -scan is specified. When set_system_mode analysis is executed and no Logic BIST configuration is detected, the -atpg sub-context is set to 1.

- -edt

  An option that returns 1 when set_context -scan is specified. When set_system_mode analysis is executed and the EDT configuration is detected, the -edt sub-context is set to 1.

- -logic_bist

  An option that returns 1 when set_context -scan is specified. When set_system_mode analysis is executed and a Logic BIST configuration is detected, the -logic_bist sub-context is set to 1.

- -rtl

  An option that returns 1 when set_context -rtl is specified.

- -no_rtl

  An option that returns 1 when set_context -no_rtl is either specified or inferred. It is inferred in all patterns contexts and in the dft -scan and -edt contexts.

- -design_identifier

  An option that returns the specified or inferred design_identifier value.

Return Value

Returns dft or patterns when no option is specified. Returns 0 or 1 when an options is specified.

Example

In the following example, a script introspects the current context and displays an appropriate message.

```
if {[get_context] == "dft"} {
   if {[get_context -scan]} {
      puts "in dft scan context"
   } elseif {[get_context -edt]} {
      puts "in dft edt context"
   } else {
      if {[get_context -rtl]} {
         puts "in dft rtl context"
      } else {
         puts "in dft no_rtl context"
      }
   }
} else { ;# patterns -> get_context is patterns
   if {[get_context -scan]} {
      if {[get_context -atpg]} {
         if {[get_context -edt]} {
            puts "in patterns scan edt atpg context"
         } else {
            puts "in patterns scan atpg context"
         }
      } else {;# logic_bist -> get_context -logic_bist is 1
         puts "in patterns scan logic_bist context"
      }
   } elseif {[get_context -ijtag]} {
      if {[get_context -extraction]} {
         puts "in ijtag icl_extraction context"
      } else {
         puts "in ijtag retargeting context"
      }
   } else {;# scan_diagnostic
      puts "in scan_diagnostic context"
   }
}
```

Related Commands

report_context

set_context

get_current_design

Context: all contexts

Mode: all modes

Usage

get_current_design [-icl]

Description

Returns a collection of one element that specifies the top-level design when previously set.

The get_current_design command returns an empty collection when the top-level design has not been previously defined using the set_current_design.

Arguments

- -icl

  An optional switch that returns the name of an ICL module object if that object exists. The switch returns an error if there is no ICL module associated with the current design.

Example

```
get_current_design
{ }

read_verilog top.v
set_current_design top
get_current_design
{top}

puts [get_current_design]
@45

puts [get_single_name [get_current_design]]
top

if { [get_single_name [get_current_design]]== "top" } { puts "yes" }
yes
```

The first get_current_design command returns an empty collection because no current design has been set. The second get_current_design command returns a collection consisting of the name of the top-level design that was previously set. The first “puts” command returns only the pointer (@45) to a collection in memory. The second “puts” command shows how to use the get_single_name command to return the name of the module object returned by get_current_design.

Related Commands

set_current_design

get_name_list

get_current_mode

Context: patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis, patterns -failure_mapping

Mode: setup, analysis

Usage

get_current_mode [-type]

Description

Returns the current mode as specified by the set_current_mode command.

If an argument is not specified with this command, the command returns the name of the mode. If the -type argument is specified, this command returns the mode type.

Arguments

- -type

  An optional switch that specifies to return the mode type. Possible return values are: unwrapped, internal, external, and retargeting. The retargeting return value applies only to the patterns -scan_retargeting and -failure_mapping contexts. For more information about these modes, see the set_current_mode command.

Example

This example returns the mode as “unwrapped”.

get_current_mode

```
unwrapped
```

Related Commands

set_current_mode

get_current_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

get_current_simulation_context

Description

Returns the name of the current simulation context.

The get_current_simulation_context command returns the current simulation context. For a list of predefined simulation contexts, refer to Table 7-40 on page 1648.

Arguments

None.

Example

The following example shows how to set and return the current simulation context:

```
SETUP> get_ current_simulation_context
stable_after_setup

SETUP> set_current_simulation_context stable_load_unload
SETUP> get_ current_simulation_context
stable_load_unload
```

delete_simulation_contexts
get_simulation_context_list
report_simulation_contexts
set_current_simulation_context

get_defaults_value

Context: unspecified, dft, patterns

Mode: setup, analysis, insertion

Usage

get_defaults_value *property_path_name*
[-policy *policy*]
[-time_unit *time_unit*] [-number_format *format*]
[-is_specified] [-tolower] [-toupper]

Description

Obtains the default value of a property as specified in one of the DefaultsSpecification/DftSpecification(company | group | user) wrappers.

When the -policy option is not specified, it returns the value specified in the DefaultsSpecification/DftSpecification's user policy, the value specified in the group policy if not specified in the user policy, the value specified in the company policy if not specified in the user or group policy, or the tool default if not specified in any policy.

Arguments

- *property_path_name*

  A required string that defines the path to a property without the "DefaultsSpecification()/" prefix.

- -policy *policy*

  An optional option value pair that defines from which DefaultsSpecification wrapper the default value is requested. If not specified, the command returns the value specified in the user policy, the value specified in the group policy if not specified in the user policy, the value specified in the company policy if not specified in the user or group policy, or the tool default if not specified in any policy.

- -time_unit *time_unit*

  An optional option value pair that is only relevant when obtaining the value of a property of type time. This option allows you to request the time expressed in the units you want. For more information see the description of the get_config_value -time_unit option.

- -number_format *format*

  An optional option value pair that is only relevant when obtaining the value of a property of type binary. This option allows you to request the binary number expressed in the format you want. For more information see the description of the get_config_value -number_format option.

- -is_specified

  An optional Boolean option that specifies that you are not requesting the actual value of the property but instead requesting status on whether the property is specified or not in the

given policy. If the -policy option is not specified, the tool returns 1 if it is specified in any of the policy wrappers. If the -policy option is not specified and the tool returns 0, then you know you are getting the tool default value.

- -tolower

  An optional option value pair that is only relevant when obtaining the value of a property of type string. This option allows you to request the string with all upper-case letters converted to lower case.

- -toupper

  An optional option value pair that is only relevant when obtaining the value of a property of type string. This option allows you to request the string with all lower-case letters converted to upper case.

Example

The following example queries the default value of a property and then checks which policy specified it:

```
> set p DftSpecification/IjtagNetwork/HostScanInterface/Block/scan_in
> get_defaults_value $p
my_scan_in
> foreach policy {user group company} {
  if {[get_defaults_value $p -policy $policy -is_specified]} {
    break
  }
}
>puts "'$p' is specified by policy $policy'."
'DftSpecification/IjtagNetwork/HostScanInterface/Block/scan_in' is
specified by policy 'group'.
```

Related Commands

set_defaults_value

create_dft_specification

get_design_level

Context: dft

Mode: setup, analysis, insertion

Usage

get_design_level

Description

Returns the design level previously defined with the set_design_level command.

When a new design is elaborated, the level goes back to being unspecified. In this case, the get_design_level command returns a null string.

Arguments

None

Example 1

The following example queries the level of the current design and stores the result in a variable.

```
set design_level [get_design_level]
```

Related Commands

set_design_level

set_current_design

get_design_sources

Context: unspecified, all contexts

Mode: setup

Usage

get_design_sources [-format { verilog | icl }] [-path_list | -extension_list]

Description

Returns the pathnames or file extensions previously specified with the set_design_sources command.

By default, the get_design_sources command returns a list of paired values that specify the pathnames to all design sources. The first item in the pair is -v or -y to indicate whether the pathname is a file or a directory, respectively. This is useful when you want to add additional design sources because any invocation of the set_design_sources command overwrites previous invocations.

Arguments

- -format { verilog | icl }

  An optional switch that allows you to choose Verilog modules or ICL modules (Tessent Shell only). By default, the command specifies Verilog modules.

- -path_list | -extension_list

  An optional switch that specifies to return either a list of pathnames or a list of file extensions. By default, the command returns a list of pathnames.

Example 1

This example returns the list of pathnames and then the list of extensions:

```
set_design_sources -y Path1 Path2 -ext EXT1 -y Path3 -ext EXT2 EXT3
get_design_sources -path_list
-y Path1 -y Path2 -y Path3

get_design_sources -extension_list
EXT1 EXT2 EXT3
```

Example 2

This example shows the difference between the set_design_sources and get_design_sources output, and demonstrates how to incrementally add to the list of design sources:

SETUP> **set_design_sources**

```
//  -------------------------------------------------------
//  List of verilog -v/-y files/directories in search order
//  -------------------------------------------------------
//  MODB.v
//  MODC.v
//  MODD.v
//  -------------------------------------------------------
```

SETUP> **get_design_sources**

```
-v MODB.v -v MODC.v -v MODD.v
```

SETUP> **set_design_sources -v MODB.v -v MODC.v**
SETUP> **get_design_sources**

```
-v MODB.v -v MODC.v
```

SETUP> **set_design_sources [get_design_sources] -v MODD.v**
SETUP> **get_design_sources**

```
-v MODB.v -v MODC.v -v MODD.v
```

report_design_sources

set_design_sources

get_dfm_rules

Context: patterns -scan_diagnosis

Mode: analysis

Usage

get_dfm_rules [-header | -col *columns*...]

Description

Returns a TCL list of the DFM rules contained in the layout database.

By default, for each rule the tool returns the id, rule name, layer, and type.

For more information about DFM rules, see "Diagnosis for Design for Manufacturability Analysis."

Arguments

- -header

  An optional switch that returns a list of available column names.

- -col *columns*...

  An optional switch that specifies the column names you want to use for the DFM rule information in the list.

Example1

The following example sets the available column names of the DFM report table into a TCL variable and displays the column names.

```
open_layout MyLayoutDB
set columns [ get_dfm_rules -header ]
puts "columns: $columns"
```

```
columns: id rule layer type
```

Example 2

The following example creates a custom report by inspecting the DFM rules:

```
foreach { id rule_name layer_name type_name }  [ get_dfm_rules ] {
    puts "$id $rule_name $layer_name $type_name"
}
```

```
1 minimum_space_4_line_route1 route_1 BRIDGE
2 metal_cross_edge_route1 route_1 OPEN
3 low_density_min_space_route2 route_2 BRIDGE
4 half_comb_route3 route_2 OPEN
5 metal_cross_edge_route1 route_3 OPEN
6 corner_to_interior_metal4 route_4 BRIDGE
7 divergent_line_with_jog_metal5 route_5 BRIDGE
8 metal_cross_edge_route1 route_5 OPEN
9 route_5_barbell route_5 OPEN
10 route_2_between_vias route_2 OPEN
```

Example 3

The following example customizes the columns for the report:

```
foreach { r t }  [ get_dfm_rules -col rule type ] {
    puts "$r $t"
}
```

```
minimum_space_4_line_route1  BRIDGE
metal_cross_edge_route1  OPEN
low_density_min_space_route2  BRIDGE
half_comb_route3  OPEN
metal_cross_edge_route1  OPEN
corner_to_interior_metal4  BRIDGE
divergent_line_with_jog_metal5  BRIDGE
metal_cross_edge_route1  OPEN
route_5_barbell  OPEN
route_2_between_vias  OPEN
```

report_dfm_rules

get_dft_cell

Context: dft

Mode: all modes

Usage

get_dft_cell -available_cell_selection_names | *function_name*
[-cell_selection_name *dft_cell_selection_name*] [-inputs number] [-silent]

Description

Retrieves the named sets of cells to use when test hardware must be inserted (as a Tcl list of the currently available cell selection names), or a particular cell given the name and desired cell function of a specified set of cells.

If only one set (one cell_selection) exists, then the name of the cell selection is optional for retrieving a cell of a given function. Otherwise, -cell_selection_name is used to identify a specific cell selection.

This command is very useful in enabling you to write a technology-independent command. After you have retrieved the cell module using the get_dft_cell command, you can use the function attribute on the ports of the module to find the ports you want to connect to.

For more information on Tessent cell library attributes, see the *Tessent Cell Library Manual*. More specifically, refer to the dft_cell_selection wrapper description described in the Cell Selection section as well as the function attribute described in Defining Pin Attributes.

You can see a list of the available DFT cell functions by using the “help get_dft_cell” command. Each of the listed functions corresponds one for one with the elements documented in the dft_cell_selection wrapper found in the Cell Selection section of the *Tessent Cell Library Manual*. Many basic functions are learned and automatically assigned to an unnamed dft_cell_selection wrapper when your library does not contain a dft_cell_selection wrapper.

Note

If your Tessent cell library contains only ATPG model information but you have a cell.lib file in the original LogicVision format, you can load it natively using the read_cell_library command and the cell_selection section will be populated.

Arguments

- -available_cell_selection_names

  An optional switch that specifies for the tool to return a Tcl list of names of the currently available DFT cell selections. If none are parsed and one is learned by default, it will return a list with the single element “default”. If there is no cell selection parsed and no default is created (for example, if no library is loaded) it will return null.

- *function_name*

  A required string that specifies the DFT cell function from the specified or default dft_cell_selection to return. If the specified function does not exist in the specified dft_cell_selection, the tool issues an error and lists the dft_cell_selection names that contains the requested function_name.

- -cell_selection_name *dft_cell_selection_name*

  A switch and string pair that specifies the name of a currently available cell selection to retrieve cells from. This could be a technology name, for example. This switch is optional if only one dft_cell_selection wrapper is currently loaded. If this switch is not specified and more than one dft_cell_selection wrapper exists, the tool issues an error. Similarly, if an invalid technology is specified, the tool issues an error and lists all available dft_cell_selection names.

- -inputs *number*

  An optional switch and integer pair that specifies the number of inputs on the model. The default number is 2. The default is ignored except in the case of symmetrical primitives {and, nand, or, nor, xor}. The default for symmetrical primitives is 2 unless the -inputs number pair specifies an integer greater than 2; in this case the tool returns a cell with the specified number of inputs if one exists in the specified technology.

- -silent

  An optional switch that specifies to suppress the error message and returns an empty collection.

Return Value

Returns the module objects when no errors are present.

Example 1

In the following example, the command queries which cell model is available in the tech_name_1 dft_cell_selection wrapper to be used as a clock_buffer.

get_dft_cell clock_buffer -cell_selection_name tech_name_1

```
{my_buff}
```

Example 2

In the following example, the command queries which 4-input cell model is available to be used as an and gate.

get_dft_cell and -input 4

```
{and_4}
```

Example 3

In the following example, multiple dft_cell_selection wrappers exist but the -cell_selection_name switch is not specified. As a result, the tool returns an error and lists the available dft_cell_selection names that exist in the library.

```
SETUP> get_dft_cell and
//  Error: Multiple cell_selection(<selection_name>) exist.
//         Must specify -cell_selection_name followed by one of :
//         tech_name_1
//         tech_name_2
//         tech_name_3
```

Example 4

In the following example, an invalid technology is specified. As a result, the tool returns an error and lists the available technologies.

```
get_dft_cell and -cell_selection_name foo
//  Error: cell_selection(foo) does not exist.
//         -cell_selection_name must currently be followed by one of :
//         tech_name_1
//         tech_name_2
//         tech_name_3
```

Example 5

In the following example, a procedure called intercept_with_cell_body is created to allow intercepting ports, nets, or pins that are either sinks or drivers. The second argument is a cell_selection type string that uses the get_dft_cell command to obtain the corresponding cell from the library, thereby making this command technology-independent. To understand the purpose of each section, read the comments in the commented section headers.

Note, in Section 3, the port attribute called ‘function’ is used to determine the port names to connect on the selected dft cell. You can also refer to the example for the register_tcl_command to see how you can create a cleaner external interface to this command with proper option parsing and help messages.

report_context

set_context

get_fanins

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Usage

get_fanins ***obj_spec*** [-stop_on cell_pin | net | pin] [-silent]

Description

Returns a collection of all requested objects found in the fanin of the specified pin, net, or port object.

When obj_spec is an output or inout pin of a cell, then the command reports all input or inout pins on the same cell that are in the combinational fanin of the output or inout pin. Note that the fanin direction of an inout pin is toward the inside of the instance, and the fanout direction of an inout pin is toward the outside of the instance.

The -stop_on option specifies object types upon which the tracing should stop. It does not mean that the returned collections contain only objects of the specified type because the tracing may stop before reaching the specified type. For example, a pin may be connected to a dangling net. The net will be reported as the object on the fanin of the pin even if -stop_on is specified as cell_pin. If the net had not been dangling and it had a driver, the get_fanins command would not have stopped on the net and would have continued to walk the fanin path.

The get_fanins command returns an empty collection when there is no fanin. The fanin of an input port is null.

The get_fanins command does not use simulated values and only considers connectivity of the hierarchical data model. You can use the trace_flat_model command to perform tracing on the flat model with simulation conditions considered.

Arguments

- ***obj_spec***

  A required value that specifies a net, pin, port, or pseudo_port name; a Tcl list of net, pin, port, or pseudo_port names; or a collection of net, pin, port, or pseudo_port objects.

- -stop_on cell_pin | net | pin

  An optional switch and literal pair that specifies the following:

  - When -stop_on is set to cell_pin (the default), the fanin walk traverses nets and design pins but stops on pins of cells or primitives in the fanin of the object. The walk may still, however, stop on a net or a design pin when the net or design pin does not have a fanin.
  - When -stop_on is set to net, the fanin walk traverses through one level of “assign” statements and stops on the net connected to the start pin.

- When -stop_on is set to pin, the fanin walk traverses nets and reports the pin in the fanin of the object. This could be an input or inout pin above the object or an output or inout pin on child instances. The walk may still, however, stop on a net if the net does not fanin to pins.

- -silent

  An optional switch that suppresses the error that is normally generated if any object within obj_spec does not exist, in which case it is ignored.

Example 1

The following example shows a series of get_fanins command invocations of the circuit example shown in Figure 7-13.

```
# find net connected to pin u4/I5
get_fanins u4/I5 -stop_on net

{n3}

#Find cell_pin in the fanin of u4/I5
get_fanins u4/I5

{u3/Y}

#Find pin in the fanin of u4/I5. Returns cell pins as there is no design pins before it
get_fanins u4/I5 -stop_on pin

{u3/Y}

#Find pin in the fanin of u4/u1/A0
get_fanins u4/u1/A0 -stop_on pin

{u4/I1}

#Find all nets connected to the D pin of dff modules
get_fanins [get_pins -filter {module_name == “dff” && leaf_name == “D”}] -stop_on net

{I3 n6 u4/n2 u4/n3 u4/u5/n1 u4/u5/I3 u5/n1}

#Find pins in the fanin of an output pin of a cell
get_fanins u1/Y

{u1/A0 u1/A1 u1/A2}
```

Example 2

The following example adds an internal primary input (pseudo_port). Based on the example circuit shown in Figure 7-13, it then returns the collection of objects found in the fanin of both of the pseudo_port’s underlying pins.

```
add_primary_inputs {u4/I4 u4/I5} -internal -pin_name user_pi1
get_fanins user_pi1

{I5 u3/Y}
```

get_fanouts

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Usage

get_fanouts ***obj_spec*** [-stop_on cell_pin | net | pin] [-silent]

Description

Returns a collection of all requested objects found in the fanout of the specified pin, net, or port object.

When obj_spec is an input pin of a cell, then the command reports all output or inout pins on the same cell that are in the combinational fanout of the input pin. Note that the fanout direction of an inout pin is toward the outside of the instance, and the fanin direction of an inout pin is toward the inside of the instance.

The -stop_on option is used to specify object types upon which the tracing should stop. Specifying this option does not mean that the returned collections will only contain objects of the specified type, because the tracing may stop before reaching the specified type. For example, a pin may be connected to a dangling net. The net will be reported as the object on the fanout of the pin even if -stop_on is specified as cell_pin. If the net had been connected to other pins, the get_fanouts command would not have stopped on the net and would have continued to walk the fanout path.

The get_fanouts command returns an empty collection when there is no fanout.The fanout of an output or inout port is null.

The get_fanouts command does not use simulated values and only considers connectivity of the hierarchical data model. You can use the trace_flat_model command to perform tracing on the flat model with simulation conditions considered.

Arguments

- ***obj_spec***

  A required value that specifies a net, pin, port, or pseudo_port name; a Tcl list of net, pin, port, or pseudo_port names; or a collection of net, pin, port, or pseudo_port objects.

- -stop_on cell_pin | net | pin

  An optional switch and literal pair that specifies the following:

  - When -stop_on is set to cell_pin (the default), the fanout walk traverses nets and design pins but stops on pins of cells or primitives in the fanout of the object. The walk may still, however, stop on a net or a design pin when the net or design pin does not have a fanout.

  - When -stop_on is set to net, the fanout walk traverses through one level of “assign” statements and stops on the net connected to the start pin,.

- When -stop_on is set to pin, the fanout walk traverses nets and reports the pin in the fanout of the object. This could be output or inout pins above the object or inputs or inout pins on child instances. The walk may still, however, stop on a net if the net does not fanout to pins.

- -silent

  An optional switch that suppresses the error that is normally generated if any object within obj_spec does not exist, in which case it is ignored.

Example 1

The following example shows a series of get_fanouts command invocations of the circuit example shown in Figure 7-14.

#Find cell pins in the fanout of u4/I5
get_fanouts u4/I5

```
{u4/u4/A2 u4/u5/u3/D}
```

#Find pins in the fanout of u4/u1/Y. Returns a cell pin as there is no design pin before it
get_fanouts u4/u1/Y -stop_on pin

```
{u4/u2/D}
```

#Find pins in the fanout of u4/u4/Y
get_fanouts u4/u4/Y -stop_on pin

```
{u4/u1/A2 u4/u5/I2}
```

#Find all nets connected to the Q pin of dff modules
get_fanouts [get_pins -filter {module_name == “dff” && leaf_name == “Q”}] -stop_on net

```
{n2 O3 u4/n3 u4/O1 u4/u5/O1 u4/u5/O2 u5/n2}
```

#Find net in fanout of a cell output pin
get_fanouts u1/Y -stop_on net

```
{n1}
```

Example 2

The following example adds an internal primary output (pseudo_port). Based on the example circuit shown in Figure 7-14, it then returns the collection of objects found in the fanout of the pseudo_port’s underlying pin.

add_primary_outputs {u4/I5} -internal
get_fanouts [get_port u4/I5 -of_type pseudo]

```
{u4/u4/A2 u4/u5/u3/D}
```

get_fault_type

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: all modes

Usage

get_fault_type

Description

Returns the current fault model type, as previously specified by the set_fault_type command.

The command returns one of the following strings: stuck, toggle, iddq, transition, path_delay, bridge, udfm.

Arguments

- None

Example 1

The following example shows how to set the fault model type and then introspect the fault model:

ANALYSIS> **set_fault_type bridge**
ANALYSIS> **get_fault_type**
bridge

Example 2

The following example loads an SDC file if the current fault model type is “transition”:

```
if {[get_fault_type] eq "transition" } {
   read_sdc myDesign.sdc
} else {
   puts "No SDC file read. Fault type is [get_fault_type]."
}
```

Related Commands

set_fault_type

get_gate_pins

Context: all contexts

Mode: setup, analysis

Prerequisites: Although you can use this command in all system modes, you can only use it with a flattened netlist. In Tessent Shell, netlist flattening typically happens when you first attempt to enter analysis mode or when you issue the create_flat_model command.

Usage

get_gate_pins [*gate_pin_id_list* | *hier_pin_name_patterns*] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent] [-of_instances *instance_objects* | -below_instances *instance_objects* | -of_pins *pin_objects* | -of_ports *port_objects*]

Description

Returns a collection of gate_pin objects found below the current design in the flat model.

The command supports arbitrary filtering based on attribute values. It also supports those options for frequently used filters.

Arguments

- *gate_pin_id_list* | *hier_pin_name_patterns*

  An optional string that specifies a list of gate_pin objects. The gate_pin_id_list is a list of gate_pin IDs (two integers separated by a period, the first integer representing a gate and the second representing a gate_pin). No wild cards are allowed in the gate_pin_id_list. If the second integer is not present, the ID specifies all pins on the gate.

  The hier_pin_name_patterns is a list of strings (wildcard patterns or regular expressions) matching hierarchical pin names. Using the hier_pin_name_patterns is equivalent to filtering on the hier_pin_name attribute.

Note

When the gate_get_pin command operates on the flat model, it removes all backslashes and white spaces from escaped identifiers. You must not include backslashes or white spaces in the *hier_pin_name_patterns* string. If you want to access the corresponding gate_pin, use the gate_pin_id attribute of the hierarchical pin object. If you want to access the gate_pin by name, use the get_name_list -remove_escaping command and switch.

- -filter *attribute_equation*

  An optional switch and string that specify to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the gate_pin object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operators used simple wild card matching versus Posix extended regular expression based on the presence of the -regexp option or not.

- -regexp

  An optional switch that directs the tool to interpret the value of the hier_pin_name_patterns argument as a regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for gate_pins matching the value of the hier_pin_name_patterns argument.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns.You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

- -of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only gate_pins associated with the specified instance_objects.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only gate_pins associated with the circuitry located underneath the specified instance_objects.

- -of_pins *pin_objects*

  An optional switch and value pair that constrains the command to return only gate_pins associated with the specified pin_objects.

- -of_ports *port_objects*

  An optional switch and value pair that constrains the command to return only gate_pins associated with the specified port_objects or pseudo_port objects.

Example 1

The following example filters the collection of all gate_pin objects based on an attribute_equation of user-defined attributes:

```
get_gate_pins -filter {myType1 || myType2 == "ABC"}
{/u1/U2/b 16.0 16.1 16.2 24.0}
```

Example 2

The following example returns the collection of all gate_pin objects matching a list of case-insensitive hierarchical pin name patterns. For more examples of pattern matching with regular expressions, refer to "Glob and Regular Expression Pattern Matching Syntax" on page 107.

```
get_gate_pins {u1/u1/a u*/b} -nocase
{/u1/U1/a /u1/U1/b /u1/U2/b /u1/U3/b /u2/U1/b}
```

Example 3

The following example returns a collection of all gate_pin objects on the gate with ID=12, the output gate_pin object (pin_index=0) on the gate with ID=14, and the gate_pin object with pin_index=2 on the gate with ID=11:

get_gate_pins { 12 14.0 11.2 }
{/u2/U1/b 12.0 14.0 /u1/U3/c}

Example 4

The following equivalent get_gate_pins commands return a collection of all gate_pin objects where the corresponding hierarchical pin name matches the wildcard pattern /u1/*/a or /u2/U1*:

get_gate_pins { /u1/*/a /u2/U1* }
{/u1/U1/a /u1/U2/a /u1/U3/a /u2/U1/b /u2/U1/c /u2/U1/a /u2/U1/y /u2/U1/z}

get_gate_pins -filter "hier_pin_name =~ /u1/*/a || hier_pin_name =~ /u2/U1*"
{/u1/U1/a /u1/U2/a /u1/U3/a /u2/U1/b /u2/U1/c /u2/U1/a /u2/U1/y /u2/U1/z}

Example 5

The following example adds to the fault list all of the gate_pin objects corresponding to the hierarchical pins matching the wildcard pattern u1/*:

add_faults [get_gate_pins u1/*]
report_faults

```
type    code    pin_pathname
----   ------   ------------------------------------
  0     UC      /u2/U1/b
  1     UC      /u2/U1/b
  0     UC      /u2/U1/c
  1     UC      /u2/U1/c
  0     UC      /u2/U1/a
  1     UC      /u2/U1/a
  0     UC      /u2/U1/y
  1     UC      /u2/U1/y
  0     UC      /u2/U1/z
  1     UC      /u2/U1/z
```

Example 6

The following examples are based on the circuit in Figure 7-13 on page 891. This example returns all of the gate pins for the specified instance u4/u2:

SETUP> **get_gate_pins -of_instances u4/u2**

```
{u4/u2/Q u4/u2/QB u4/u2/CLK u4/u2/D}
```

This example returns all of the gate pins named D that are found below the u4 level of hierarchy:

SETUP> **get_gate_pins */D -below_instances u4**

```
{u4/u2/D u4/u3/D u4/u5/u2/D u4/u5/u3/D}
```

get_icl_extraction_options

Context: all contexts

Mode: all modes

Usage

get_icl_extraction_options -extract_learned_muxes | -extract_library_muxes

Description

Provides access to the settings specified by the set_icl_extraction_options command.

Arguments

- -extract_learned_muxes

  A switch that instructs the tool to return the extract_learned_muxes setting of the ICL extraction options. Possible values are 0 and 1.

- -extract_library_muxes

  A switch that instructs the tool to return the extract_library_muxes setting of the ICL extraction options. Possible values are 0 and 1.

Example

The following command returns the setting specified by the –extract_library_muxes option of set_icl_extraction_options command:

get_icl_extraction_options –extract_library_muxes

```
1
```

Related Commands

set_icl_extraction_options
report_icl_extraction_options

get_icl_fanins

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Usage

get_icl_fanins ***obj_spec*** [-stop_on none | pin] [-silent]

Description

Returns a collection of all requested objects found in the fanin of the specified pin or port objects.

The -stop_on option is used to specify object types that the tracing should stop on. Specifying this option does not mean that the returned collections will only contain objects of the specified type because the tracing may stop before reaching the specified type. For example, a pin may be directly connected to a port. The port will be reported as the object on the fanin of the pin even if -stop_on is specified as pin.

Arguments

- ***obj_spec***

  A required value that specifies an ICL pin or port name; a Tcl list of ICL pin or port names; or a collection of ICL pin or port objects.

- -stop_on none | pin

  An optional switch and literal pair that specifies the following:

  none — The fanin walk traverses the connections and the pins in the fanin of the object. The trace reports pins with no fanin or ports reached in the fanin walk.

  pin — The fanin walk traverses the connection and reports the pin in the fanin of the object; this could be an input pin above the object or an output pin on child instances. The walk may still, however, stop on a port if the pin does not fanin to pins.

- -silent

  An optional switch that suppresses the error that is normally generated if any object within obj_spec does not exist, in which case it is ignored.

Example

The following example shows command invocations with and without the -stop_on pin option to illustrate its effect.

```
# find true fanin of pin block1.sib1.s1
get_icl_fanins block1.sib1.s1

{si} # Went thought block1.si as -stop_on was defaulted to none. Reached
ICL port si on the current_design
```

```
# find first pin in fanin of block1.sib1.s1
```
get_icl_fanins block1.sib1.s1 -stop_on pin

```
{block1.si} # Stopped on block1.si as -stop_on was specified as pin.
```

Related Commands

get_icl_fanouts

Context: all contexts

Mode: all modes

Prerequisites: The current design must be set.

Usage

get_icl_fanouts ***obj_spec*** [-stop_on none | pin] [-silent]

Description

Returns a collection of all requested objects found in the fanout of the specified ICL pin, or port objects.

The -stop_on option is used to specify object types that the tracing should stop on. Specifying this option does not mean that the returned collections will only contain objects of the specified type because the tracing may stop before reaching the specified type. For example, a pin may be directly connected to a port. The port will be reported as the object on the fanout of the pin even if -stop_on is specified as pin.

Arguments

- ***obj_spec***

  A required value that specifies an ICL pin or port name; a Tcl list of ICL pin or port names; or a collection of ICL pin or port objects.

- -stop_on none | pin

  An optional switch and literal pair that specifies the following:

  none — The fanout walk traverses the connections and the pins in the fanout of the object. The trace will report pins with no fanout or ports that were reached in the fanout walk.

  pin — The fanout walk traverses the connection and reports the pin in the fanout of the object. This could be an output pin above the object or an input pin on child instances. The walk may still, however, stop on a port if the pin does not fanout to pins.

- -silent

  An optional switch that suppresses the error that is normally generated if any object within obj_spec does not exist, in which case it is ignored.

Example

The following example shows the get_icl_fanouts command invocations with and without the -stop_on pin option to illustrate its effect.

```
# find true fanout of pin block1.sib1.so
get_icl_fanins block1.sib1.so
```

```
{so} # Went thought block1.so as -stop_on was defaulted to none. Reached
ICL port so on the current_design

# find first pin in fanout of block1.sib1.so
```
get_icl_fanins block1.sib1.so -stop_on pin

```
{block1.so} # Stopped on block1.so as -stop_on was specified as pin.
```

Related Commands

get_fanins
get_icl_ports
get_icl_pins

get_icl_instances

Context: all contexts

Mode: all modes

Usage

Usage 1: Without the -hierarchical option

get_icl_instances [*name_patterns*] [-of_modules *obj_spec*]
[-parent_of_instances *instance_objects* | -below_instances *instance_objects* |
-of_pins *icl_pin_objects*]
[-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Usage 2: With the -hierarchical option

get_icl_instances [*leaf_name_patterns*] [-of_modules *obj_spec*]
[-parent_of_instances *instance_objects* | -below_instances *instance_objects*]
[-hierarchical] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Usage 3: With no name pattern

get_icl_instances [-of_modules *obj_spec*]
[-parent_of_instances *instance_objects* | -below_instances *instance_objects* |
-of_pins *icl_pin_objects*]
[-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all ICL instances instantiated relative to the current design that match the specified *name_patterns list or -filter expression.

Usage 1: The name patterns are expressed as hierarchical instance path names relative to the current design. You can have any number of wildcards or regular expressions in the names between the hierarchy separator symbols as shown in the examples for this command. You can use the dot or the slash as the hierarchy separator when not using the -regexp option. You can only use the slash as the hierarchy separator when using the -regexp option because the dot is the wildcard symbol when using regular expressions.

Usage 2: The name patterns are leaf instance names with any number of wildcards or regular expressions. Unlike in Usage 1, the leaf instance name pattern is searched relative to all ICL instances found below the current design.

Usage 3: A name_patterns argument is not specified so that all ICL instances are selected and then filtered by the other criteria specified by the other optional arguments.

If you issue this command but have not previously loaded any icl files, it will return an empty collection.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ICL instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all ICL instances that match the results returned by the -filter attribute_equation filter as shown in Usage 3. In Usage 2, described previously, the name patterns cannot include slashes or dots which are hierarchy separator symbols. In Usage 1, you can use the dot or slash as the hierarchy separator when not using the -regexp option. You can only use the slash as the hierarchy separator when using the -regexp option because the dot is the wildcard symbol when using regular expressions.

- -of_modules *obj_spec*

  An optional switch and value pair that constrains the command to return only instances of ICL modules specified by *obj_spec*. The *obj_spec* is a single ICL module name, a Tcl list of ICL module names, or a collection of ICL module objects as returned by the get_icl_modules command.

- -parent_of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return a collection of ICL instance objects that are the parent instances of the specified instance_objects. The returned collection is filtered to only return a given parent instance once. When this option is specified, the optional name_patterns option is a string that is matched against the leaf instance name of every parent instance of the collection. An error is generated if the specified name_patterns contain more than one level of hierarchy when the -parent_of_instances option is used.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for ICL instances below the specified instance_objects. The specified name_patterns are searched relative to each instance found in the instance_objects list.

- -of_pins *icl_pin_objects*

  An optional switch and value pair that constrains the command to return the ICL instance to which the ICL pins belong. The returned collection is filtered to return any given ICL instance only once, even if the instance belongs to many ICL pins in the icl_pin_objects list. When this option is specified, the optional name_patterns must be leaf_name patterns that are checked against the leaf name of the ICL instances. An error is generated if the specified name_patterns contains more than one level of hierarchy when the -of_pins option is used.

- -hierarchical

  An optional string that specifies to perform pattern matching relative to all ICL instances found below the current design. When this option is specified, the name_patterns argument cannot include slashes or dot which are hierarchy separator symbols.

- -filter *attribute_equation*

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the ICL instance object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on the filtering attribute equation format.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument and the arguments of the =~ and !~ -filter expressions as regular expressions instead of as simple wildcard patterns. You must properly escape the bracket "[]" symbols so that they are interpreted as part of the regular expression and not interpreted by the Tcl shell. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax. You must use the slash as a hierarchy separator when using the -regexp option.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for instances matching the *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

The following example illustrates Usage 3 and returns the collection of all instances of ICL modules modb and modd found anywhere below the current design:

get_icl_instances -of_modules {modb modd}

```
{u2 u1/u5}
```

Example 2

The following example illustrates Usage 3 in which the collection of all instances is filtered based on an attribute_equation of user-defined attributes.

get_icl_instances -filter {myType1 || myType2 == "ABC"}

```
{u2 u1.u5}
```

Example 3

The following example illustrates Usage 1 in which the collection of all instances matching a list of hierarchical name patterns is returned. The names u1/* and u*/u* are only searched relative to the current design.

get_icl_instances {u1/* u*/u*}

```
{u4.u5 u1.u7}
```

Example 4

The following example illustrates Usage 2 in which the collection of all instances matching a leaf name pattern is returned. The leaf instance name u3* searches for all instances found below the current design.

get_icl_instances u3* -hierarchical

```
{u3 u4.u30 u4.u5.u31 u5.u3}
```

Related Commands

get_icl_modules
get_icl_pins

get_icl_modules

Context: all contexts

Mode: all modes

Usage

get_icl_modules [*name_patterns*] [-of_instances *instance_objects* |
-below_instances *instance_objects*] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all ICL modules that match the specified name_patterns list or -filter expression.

By default, this command returns all ICL modules below the current design. You can use the -of_instances argument to constrain the search.

You can have any number of wildcards or regular expressions in the name patterns.

If you issue this command but have not previously loaded any icl files, it will return an empty collection.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ICL modules. If no name_patterns are specified, the tool searches all ICL modules that match the results returned by the -filter attribute_equation filter.

- -of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only ICL modules of the specified *instance_objects*. The instance_objects is a single ICL instance name, a Tcl list of ICL instance names, or a collection of ICL instance objects as returned by the get_icl_instances command. You could use the module_name attribute of the instance objects to perform a similar filtering but this method is more direct and efficient.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only ICL modules corresponding to instances found below the specified *instance_objects*.

- -filter *attribute_equation*

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the ICL module object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument and the arguments of the =~ and !~ -filter expressions as regular expressions instead of as simple wildcard patterns. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for modules matching the name_patterns.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

The following example returns ICL modules whose name matches a* or b*.

get_icl_modules {a* b*}

```
{ab abc b bcd}
```

Example 2

The following example returns ICL modules having one or two characters.

get_icl_modules {[:alnum:]{1,2}} -regexp

```
{ab b}
```

get_icl_module_parameter_list

Context: all contexts

Mode: all modes

Usage

get_icl_module_parameter_list ***module_object*** [-overridden]

Description

Returns the list of parameters in an ICL module.

Arguments

- ***module_object***

  A required string that specifies the parameterized ICL module objects whose parameters are to be returned.

- -overridden

  An optional switch that specifies to only list those parameters whose default values are overridden during an instantiation.

Return Value

List of parameters.

Example

n the following example, this command is used to obtain the list of parameters overridden in the specific instantiation. Notice how the get_icl_instances command is used to find the ICL instance u1/myinst_i1; this ensures that the get_attribute_value_list command returns the module_name attribute of the ICL instance and not the design instance in case a design instance of the same name exists.

```
set icl_inst [get_icl_instance u1/myinst_i1]
set params [get_icl_module_parameter_list [get_attribute_value_list $icl_inst\
                -name module_name] -overridden]
```

Related Commands

get_icl_module_parameter_value

get_icl_module_parameter_value

Context: all contexts

Mode: all modes

Usage

get_icl_module_parameter_value ***parameter_name*** [-of_module *icl_module_object*]

Description

Returns the value of the parameter on the specified module and indicates whether it is the default value or is overridden.

Arguments

- ***parameter_name***

  A required string that specifies the name of the parameter whose value is to be returned.

- -of_module *icl_module_object*

  An optional switch and string pair that specifies the ICL module whose parameter value is to be returned. When omitted, the paramters of the current design are introspeced.

Return Value

The value of the requested ICL module parameter.

Example

In the following example, the values of all overridden parameters are echoed in the transcript. Notice how the get_icl_instances command is used to find the ICL instance u1/myinst_i1; this ensures that the get_attribute_value_list command returns the module_name attribute of the ICL instance and not the design instance in case a design instance of the same name exists.

```
set icl_inst [get_icl_instance u1/myinst_i1]
set icl_mod [get_attribute_value_list $icl_inst -name module_name]
set params [get_icl_module_parameter_list $icl_mod -overridden]
foreach param $params {
        puts “parameter $param = [get_icl_module_parameter_value $param \
            -of_mod $icl_mod]”
}
```

Related Commands

get_icl_module_parameter_list

get_icl_pins

Context: all contexts

Mode: all modes

Usage

Usage 1: Without the -hierarchical option

get_icl_pins *name_patterns* [-direction input | output]
[-function *function*]
[-of_instances *instance_objects* | -below_instances *instance_objects*]
[-filter *attribute_equation*]
[-regexp] [-nocase] [-silent]

Usage 2: With the -hierarchical option

get_icl_pins *leaf_name_patterns* | *leaf_instance/leaf_name_patterns* -hierarchical
[-below_instances *instance_objects*] [-filter *attribute_equation*]
[-direction input | output] [-function *function*]
[-regexp] [-nocase] [-silent]

Usage 3: With no name pattern

get_icl_pins [-filter *attribute_equation*] [-direction input | output] [-function *function*] [-regexp]
[-nocase] [-silent]

Description

Returns a collection of all hierarchical ICL pins instantiated relative to the current design that match the specified name_patterns list or -filter expression.

Usage 1: The name patterns are expressed as hierarchical pin pathnames relative to the current design. You can have any number of wild cards or regular expressions in the names between the hierarchy separator symbols as shown in the examples that follow. You can use the dot or the slash as the hierarchy separator when not using the -regexp option. You can only use the slash as the hierarchy separator when using the -regexp option because the dot is the wildcard symbol when using regular expressions.

Usage 2: The name patterns are leaf pin names or leaf instance name/leaf pin names with any number of wildcards or regular expressions. Unlike in Usage 1, the leaf name pattern is searched relative to all instances found below the current design. There can only be one hierarchy separator when using the -hierarchical option as shown in Example 3.

Usage 3: A name_patterns argument is not specified so all ICL pins are selected and then filtered by the other criteria specified by the other optional arguments.

If you issue this command but have not previously loaded any icl files, it will return an empty collection.

Arguments

- *name_patterns | leaf_instance/leaf_name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of pins. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all ICL pins that match the results returned by the -filter attribute_equation filter as shown in Usage 3. In Usage 2, described previously, the name patterns are not allowed to include more than one slash or dot which are hierarchy separator symbols. See section "Attribute Filtering Equation Syntax" on page 105 for a complete description of the pattern syntax when the -regexp option is used or not.

- -direction input | output

  An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the pin object. When omitted, pins with any direction are considered.

- -of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only ICL pins of the specified instance_objects. The instance_objects is a single ICL instance name, a Tcl list of ICL instance names, or a collection of ICL instance objects as returned by the get_icl_instances command. You could use the module_name attribute of the instance objects to perform a similar filtering but this method is more direct and efficient.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for ICL pins below the specified *instance_objects.* Specified name_patterns are searched relative to the specified *instance_objects* when this option is used.

- -hierarchical

  An optional string that specifies to perform pattern matching relative to all ICL instances found below the current design. When this option is specified, the name_patterns argument cannot include more then one slash or dot which are the hierarchy separator symbols.

- -function *function*

  An optional switch and literal pair that specifies to filter results based on the value of the function attribute on the ICL pin object. When omitted, pins with any function are considered. The value *function* is a Tcl list of function names derived from the ICL port function where multiple words are separated by underscores instead of using camel casing. For example, a port declared as a ScanInPort in ICL has function scan_in in the ICL data model.

- -filter *attribute_equation*

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the ICL pin object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operator use

simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the *name_patterns* argument and the arguments of the =~ and !~ -filter expressions as regular expressions instead of as simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ICL pin names matching *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

The following example illustrates Usage 3 where the collection of all ICL pins is filtered based on an attribute_equation of user-defined attributes.

get_icl_pins -filter {myType1 || myType2 == "ABC"}

```
{u1.Y u4.u4.A0 u7.D}
```

Example 2

The following example illustrates Usage 1 where the collection of all ICL pins matching a list of hierarchical name patterns is returned. The names u1/Y and u*/Q are only searched relative to the current design. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for examples of pattern matching with regular expressions.

get_icl_pins {u1/Y u*/Q}

```
{u1.Y u2.Q u7.Q}
```

Example 3

The following example illustrates Usage 2 where the collection of all ICL pins matching a leaf instance_name/leaf pin name pattern is returned. The tool searches for the leaf instance name u* in all ICL instances found below the current design, and then searches for the leaf pin names matching Y* on those instances.

get_icl_pins u*/Y* -hierarchical

```
{u1.Y u3.Y u4.u1.Y u4.u4.Y u4.u5.u1.Y u5.u1.Y u5.u3.Y u5.u4.Y u6.Y}
```

Example 4

The following example gets all ICL pins with function clock or to_clock in the ICL data base.

get_icl_pins -function {clock to_clock}

```
{PLL1.ref PLL1.vco mbist.clk}
```

Related Commands

get_common_parent_instance
get_icl_ports
get_iproc_argument_default
read_icl

get_icl_ports

Context: all contexts

Mode: all modes

Usage

get_icl_ports [*name_patterns*] [-of_modules *obj_spec*] [-direction input | output] [-function *function*] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all ports on a given module that match the specified name_patterns list or -filter expression.

You can have any number of wildcards or regular expressions in the name patterns.

If you issue this command but have not previously loaded any icl files, it will return an empty collection.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ports. If no name_patterns are specified, the tool searches all ports that match the results returned by the -filter attribute_equation filter, if one is specified.

- -of_modules *obj_spec*

  An optional switch and value pair that constrains the command to return only ports on modules specified by *obj_spec*. The *obj_spec* is a single ICL module name, a Tcl list of ICL module names, or a collection of one or more module objects as returned by the get_icl_modules command.

- -direction input | output

  An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the port object. When omitted, ports with any direction are considered.

- -function *function*

  An optional switch and literal pair that specifies to filter results based on the value of the function attribute on the ICL port object. When omitted, ports with any function are considered. The value *function* is a Tcl list of function names derived from the ICL port function where multiple words are separated by underscores instead of using camel casing. For example, a port declared as a ScanInPort in ICL has function scan_in in the ICL data model.

- -filter *attribute_equation*

  An optional switch and string that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the ICL port object type. See section “Attribute Filtering Equation Syntax” on page 105 for

more details on filtering attribute equation format. The =~ and !~ matching operators used simple wild card matching versus Posix extended regular expression based on the presence of the -regexp option or not.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument and the arguments of the =~ and !~ -filter expressions as regular expressions instead of as simple wildcard patterns. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ports matching the *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

This example looks for ICL ports on the current design whose name match I* or O*.

get_icl_ports {I* O*}

```
{I1 I2 I3 I4 I5 I6 I7 I8 O1 O2 O3}
```

Example 2

This example looks for scalar ports having one or two characters on module ModA.

get_icl_ports {[[:alnum:]]{1,2}} -regexp -of_module ModA

```
{ab a b}
```

Related Commands

get_common_parent_instance
get_icl_pins
get_iproc_argument_default
read_icl

get_icl_scan_interface_list

Context: dft, patterns -ijtag

Mode: setup, analysis

Usage

get_icl_scan_interface_list

Description

Returns the names of the scan interfaces in an existing ICL top module, if the ICL top module exists. If the ICL top module does not exist, it returns the names of the scan interfaces that will be created in the new ICL top module by ICL extraction after the add_icl_scan_interfaces command has been used to specify the scan interfaces.

You must set the current design with set_current_design before using the get_icl_scan_interface_list command.

Arguments

- None

Return Value

If the ICL top module exists, this command returns the ScanInterface names in the ICL top module. If the module does not have an explicit ScanInterface definition in the ICL module, but only an implicitly defined anonymous scan interface, the command returns “unnamed”. If the ICL top module does not exist, the command returns the new ScanInterface names specified with the add_icl_scan_interfaces command, which will be created during ICL extraction.

Example

The following example returns the ScanInterface names PG1 and PG2 in the ICL module pass1:

```
Module pass1 {
   ScanInPort sin1;
   ScanInPort sin2;
   ScanOutPort sout;
   ShiftEnPort sen;
   CaptureEnPort cen;
   SelectPort select1;
   SelectPort select2;
   UpdateEnPort uen;
   ScanInterface PG1 {
        Port sin1; Port sout; Port sen; Port cen; Port select1; Port uen;
   }
   ScanInterface PG2 {
        Port sin2; Port sout; Port sen; Port cen; Port select2; Port uen;
   }
}
```

set_current_design pass1

get_icl_scan_interface_list

```
PG1 PG2
```

Related Commands

add_icl_scan_interfaces
delete_icl_scan_interfaces
get_icl_scan_interface_port_list
set_icl_scan_interface_ports

get_icl_scan_interface_port_list

Context: dft, patterns -ijtag

Mode: setup, analysis

Usage

get_icl_scan_interface_port_list **-name** ***name***

Description

Returns the names of the ports for the specified scan interface in an existing ICL top module, or the names of the ports for the specified scan interface that will be created in the new ICL top module during ICL extraction.

You must set the current design with set_current_design before using the get_icl_scan_interface_port_list command.

Arguments

- **-name** ***name***

  A required switch and value pair that specifies the name of scan interface for which the list of ports will be returned. If the module does not have an explicit ScanInterface definition in the ICL module, then it has an implicitly defined anonymous scan interface. In this case, use the string “unnamed” for the scan interface name to get the ports of the anonymous scan interface.

Return Value

If the ICL top module exists, this command returns the names of the ports for the specified ScanInterface.

If the ICL top module does not exist, the command returns the names of the new ports for the ScanInterface specified with the set_icl_scan_interface_ports command, which will be created during ICL extraction.

Example 1

This example returns the list of ports for the ScanInterface named default in the ICL module pass1:

```
Module pass1{
   ScanInPort sin;
   ScanOutPort sout;
   SelectPort select;
   CaptureEnPort cen;
   ShiftEnPort shiftEn;
   UpdateEnPort updateEn;
   ScanInterface default {
      Port sin; Port sout; Port select; Port cen; Port shiftEn; Port
updateEn; DefaultLoadValue 3'b0;
   }
```

set_current_design pass1

get_icl_scan_interface_port_list -name default

```
sin sout select cen shiftEn updateEn
```

Example 2

This example returns the list of ports for the anonymous scan interface in the ICL module pass2:

```
Module pass2{
   ScanInPort sin;
   ScanOutPort sout;
   SelectPort select;
   CaptureEnPort cen;
   ShiftEnPort shiftEn;
   UpdateEnPort UpdateEn;
   }
```

set_current_design pass2

get_icl_scan_interface_port_list -name unnamed

```
sin sout select cen shiftEn updateEn
```

delete_icl_scan_interfaces
get_icl_scan_interface_list
set_icl_scan_interface_ports

get_icl_scope

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

get_icl_scope [-iCall | -iPrefix]

Description

Introspects the current ICL scope.

When executed without an option, this command returns the instance name prefix that will be appended to the beginning of any ICL object names used in the iCall, iWrite, and iRead commands. When executed with the -iCall option, this command ignores the current iPrefix specification and returns the ICL scope against which the current iProc is running. When executed with the -iPrefix option, this command returns the current value specified for the iPrefix command.

For more information on the ICL scope, see the iCall command reference page.

Arguments

- -iCall

  An optional literal that specifies to ignore the current iPrefix specification and return the ICL scope against which the current iProc is running. This path is useful to obtain the exact ICL instance the iProc was executed against using the iCall command. You can use this value in an iNote as shown in the example below.

- -iPrefix

  An optional literal that specifies to return the current value specified for the iPrefix command.

Return Value

An ICL instance path name.

Example

In the following example, the iProc gets the ICL scope in which it was executed against with the iCall command to echo into the retargeted pattern using an iNote command:

```
iProc myProc {} {
        iNote “Running on Instance [get_icl_scope -iCall]”
}
```

Related Commands

iCall

iPrefix

get_iclock_list

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

get_iclock_list [-overridden]

Description

Returns a list of ICL port and pin names on which you have issued an iClock command.

When you use the -overridden option, this command lists the ICL port and pin names on which you have issued an iClockOverride command on. You can use this list to introspect the effective source and the effective frequency multiplication and division values of the ICL pin or port using the get_iclock_option [-overridden] command.

Arguments

- -overridden

  Specifies to return the ICL port and pin names on which an iClockOverride command was issued as opposed to the iClock command when the option is not specified.

Return Value

A Tcl list of ICL port and pin names.

Example

In the following example, a Tcl list of ICL port and pin names are obtained using the get_iclock_list command. Their effective source and their effective frequency multiplication and division values are then echoed to the transcript

```
set iclock_list [get_iclock_list]
foreach iclock $iclock_list {
        puts “iClock pin or port: $iclock”
        puts “ source = [get_iclock_option $iclock -source]”
        puts “ freq_multiplier= [get_iclock_option $iclock -freq_multiplier]”
        puts “ freq_divider = [get_iclock_option $iclock -freq_divider]”
}
```

Related Commands

report_icl_modules

get_iclock_option

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

get_iclock_option ***icl_port_or_pin_name*** [-overridden]
{**-source** | **-freq_multiplier** | **-freq_divider** | **-period** [-in { fs | ps | ns | us | ms | s }] }

Description

Returns the effective or specified source, frequency multiplier, frequency divider, or clock period values for the specified icl_port_or_pin_name.

The specified icl_port_or_pin_name must have been the target of an iClock command when the -overridden option is not specified; it must have been the target of an iClockOverride command when the -overridden option is specified.

- ***icl_port_or_pin_name***

  A required string that specifies the name of an ICL port or pin object on which an iClock or iClockOverride command has been issued.

- -overridden

  An optional switch that specifies that icl_port_or_pin_name must be an ICL port or pin object on which an iClockOverride command has been issued. When you use this switch, you cannot also use the -period switch.

- **-source**

  A required switch that specifies to return the effective source of an iClock ICL pin or port, or the specified source of an iClockOverride ICL pin or port.

- **-freq_multiplier**

  A required switch that specifies to return the effective frequency multiplier value of an iClock ICL pin or port, or the specified frequency multiplier value of an iClockOverride ICL pin or port.

- **-freq_divider**

  A required switch that specifies to return the effective frequency divider value of an iClock ICL pin or port, or the specified frequency divider value of an iClockOverride ICL pin or port.

- **-period** [-in { fs | ps | ns | us | ms | s }]

  A required switch that returns the clock period of the specified icl_port_or_pin_name. You can optionally use the -in switch and keyword to specify a particular time unit. When you use the -period switch, you cannot also use the -overridden switch. By default, the time unit is derived from the time unit of the source clock. This is either the time unit used in the -period switch of the add_clocks command (in case of an asynchronous source clock) or the time unit of the tester period (in case of a synchronous source clock).

Return Value

The value of the specified option for the specified icl_port_or_pin_name.

Example

In the following example, a Tcl list of ICL port and pin names are obtained using the get_iclock_list command. Their effective source and their effective frequency multiplication and division values are then echoed to the transcript

```
set iclock_list [get_iclock_list]
foreach iclock $iclock_list {
        puts “iClock pin or port: $iclock”
        puts “ source = [get_iclock_option $iclock -source]”
        puts “ freq_multiplier= [get_iclock_option $iclock -freq_multiplier]”
        puts “ freq_divider = [get_iclock_option $iclock -freq_divider]”
}
```

get_ijtag_instances

Context: dft, patterns

Mode: all modes

Usage

get_ijtag_instances [*name_spec*] [-below_instances *instance_objects*]
[-filter *attribute_equation*] [-silent]

Description

Returns a collection of instances for which there is a matched ICL module.

You can restrict the search to instances below a given collection of instances and filter the collection based on an arbitary filtering equation involving other attributes registered against or inherited by the instance object type.

The -silent option suppresses the warning that is normally generated if no Ijtag instances are returned.

Arguments

- ***name_spec***

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all Ijtag instances.

  If you specify the -below_instances options, the name patterns are hierarchical name patterns relative to the specified instance objects; otherwise the name patterns are relative to the current design.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for instances below the specified instance_objects. The specified name_patterns are searched relative to each instance found in the instance_objects list.

- -filter *attribute_equation*

  An optional switch and string that specify to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the instance object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering using the attribute equation format.

- -silent

  An optional switch that suppresses the warning message normally generated when the command returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example

The following example uses the get_ijtag_instances command to get all instances of a module below a given instance for which there is a matched ICL file.

```
> get_ijtag_instances -below_instance subblockA_i1
{subblockA_i1/tdr1 subblockA_i1/tdr2}
```

Related Commands

get_ijtag_instance_option

set_ijtag_instance_options

report_ijtag_instances

get_ijtag_instance_option

Context: dft, patterns

Mode: all modes

Usage

get_ijtag_instance_option **ijtag_instance** [-use_in_dft_specification]

Description

Returns the value of the selected option for the specified Ijtag instance.

Arguments

- ***ijtag_instance***

  A required literal that is the name of an ijtag instance or a collection containing one ijtag instance as reported by get_instances or get_ijtag_instances.

  The instance object must have an ICL module matched to it.

- -use_in_dft_specification

  A Boolean option that specifies that the value of the -use_in_dft_specification option is required. This value is set using the set_ijtag_instance_options and is used by the create_dft_specification command.

Example

The following example returns the value of the use_in_dft_specification option of all Ijtag instances.

```
> foreach_in_collection inst [get_ijtag_instances] {
  set opt [get_ijtag_instance_option $inst -use_in_dft_spec]
  puts "inst = [get_single_name $inst], use_in_dft_spec = $opt"
}
inst = u1/trd1, use_in_dft_spec = auto
inst = u1/trd2, use_in_dft_spec = auto
inst = u2/trd1, use_in_dft_spec = off
```

Related Commands

get_ijtag_instances

set_ijtag_instance_options

report_ijtag_instances

get_ijtag_retargeting_options

Context: all contexts

Mode: all modes

Usage

get_ijtag_retargeting_options -test_setup_network_end_state |
-compare_constant_capture_values | -compare_constant_data_out_ports

Description

Returns the value of the specified option of the previous set_ijtag_retargeting_options command or its default value if the set_ijtag_retargeting_options command was not issued.

To use this command, you must have previously loaded and elaborated the top-level ICL module. Otherwise, the tool issues an error message.

Arguments

- -test_setup_network_end_state

  A switch that returns the value of the -test_setup_network_end_state option (keep or reset) specified by the previous set_ijtag_retargeting_options command or returns the default value (reset) if the set_ijtag_retargeting_options command was not issued.

- -compare_constant_capture_values

  A switch that returns the value of the -compare_constant_capture_values option (on or off) specified by the previous set_ijtag_retargeting_options command or returns the default value (on) if the set_ijtag_retargeting_options command was not issued.

- -compare_constant_data_out_ports

  A switch that returns the value of the -compare_constant_data_out_ports option for the primary DataOut ports (on or off) specified by the previous set_ijtag_retargeting_options command or returns the default value (off) if the set_ijtag_retargeting_options command was not issued.

Example

The following example loads the ICL, turns off the reset of the ICL network after the last test_setup PDL command and then displays the value of the selected option:

```
SETUP> set_context patterns -ijtag -no_rtl
SETUP> read_icl ../data/chip.icl
SETUP> set_current_design

//  Note: Top design is 'chip'.

SETUP> set_ijtag_retargeting_options -test_setup_network_end_state keep

set_ijtag_retargeting_options

get_insertion_option

Context: unspecified, all contexts

Mode: all modes

Usage

get_insertion_option {-auto_uniquify_edited_modules | -edited_module_prefix | -net_uniquification_suffix | -module_uniquification_suffix | -instance_uniquification_suffix | -allow_assigns | -inserted_object_comment_label}

Description

Returns the value of any insertion option that is specifiable with the set_insertion_options command.

Only one option can be specified per get_insertion_option invocation. The return value is a string containing the current setting of the specified option. An error is generated if more than one option is specified, and the return value will be null.

Arguments

- -auto_uniquify_edited_modules

  A switch that returns the current setting of -auto_uniquify_edited_modules option of the set_insertion_options command.

- -edited_module_prefix

  A switch that returns the current setting of the -edited_module_prefix option of the set_insertion_options command.

- -net_uniquification_suffix

  A switch that returns the current setting of the -net_uniquification_suffix option of the set_insertion_options command.

- -module_uniquification_suffix

  A switch that returns the current setting of the -module_uniquification_suffix option of the set_insertion_options command.

- -instance_uniquification_suffix

  A switch that returns the current setting of the -instance_uniquification_suffix option of the set_insertion_options command.

- -allow_assigns

  A switch that returns the current setting of the -allow_assigns option of the set_insertion_options command.

- -inserted_object_comment_label

  A switch that returns the current setting of the -inserted_object_comment_label option of the set_insertion_options command.

Example

The following example introspects the current setting of the -edited_module_prefix option of the set_insertion_options command.

get_insertion_option -edited_module_prefix

```
MyCore_
```

Related Commands

set_insertion_options

get_insert_test_logic_options

Context: dft -test_points

Mode: setup, analysis

Usage

get_insert_test_logic_options [**-inserted_object_prefix**]

Description

Retrieves the current prefix that will be used when creating test point logic.

The command returns an empy string if no option is specified.

Arguments

- **-inserted_object_prefix**

  A required switch that returns the prefix set with the set_insert_test_logic_options command. If no user-defined prefix has been set, the default prefix “ts_” is returned.

Example

The following example shows how to determine the prefix that will be used when inserting nets and instances during test point insertion. In this case, the command will return "demo1_" because of the previous set_insert_test_logic_options command.

```
set_insert_test_logic_options -inserted_object_prefix demo1_
insert_test_logic
write_design -output netlist.v -replace
set prefix [get_insert_test_logic_options -inserted_object_prefix]
puts "inserted nets and instances will be prefixed with : $prefix"
```

Related Commands

set_insert_test_logic_options

get_instances

Context: all contexts

Mode: all modes

Usage

get_instances [*name_patterns*] [-of_modules *module_objects*]
[-parent_of_instances *instance_objects* | -below_instances *instance_objects* |
-of_pins *pin_objects* | -of_nets *net_objects*]
[-of_type *types*] [-hierarchical] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all instances instantiated relative to the current design that match the specified name_patterns list, subject to filtering imposed by the other optional options.

When the name_patterns list is omitted, all instances are returned subject to filtering imposed by the other optional options.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all instances.

  If you specify one of the optional switches (-parent_of_instances, -of_pins, -of_nets, or -hierarchical), the name patterns are matched against the leaf_name attribute value of the instances in which case no hierarchy separators are allowed in the pattern list.

  If you specify the -below_instances options, the name patterns are hierarchical name patterns relative to the specified instance objects otherwise the name patterns are relative to the current design.

- -of_modules *module_objects*

  An optional switch and value pair that constrains the command to return only instances of modules specified by module_objects. The module_objects is a single module name, a Tcl list of module names, or a collection of module objects as returned by the get_modules command.

- -parent_of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return a collection of instance objects that are the parent instances of the specified instance_objects. The returned collection is filtered to only return a given parent instance once. When this option is specified, the optional name_patterns option is a string that is matched against the leaf instance name of every parent instance of the collection. An error is generated if the specified name_patterns contain more than one level of hierarchy when the -parent_of_instances option is used.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for instances below the specified instance_objects. The specified name_patterns are searched relative to each instance found in the instance_objects list.

- -of_pins *pin_objects*

  An optional switch and value pair that constrains the command to return the instance on which the pins belong to. The returned collection is filtered to only return a given instance once even if it belongs to many pins in the pin_objects list. When this option is specified, the optional name_patterns is a string that is matched against the leaf instance name of the instances. An error is generated if the specified name_patterns contain more than one level of hierarchy when the -of_pins option is used.

- -of_nets *net_objects*

  An optional switch and value pair that constrains the command to return the instance in which the net objects are located. The returned collection is filtered to only return a given instance once even if it is the parent instance of many nets in the net_objects list. When this option is specified, the optional name_patterns is a string that is matched against the leaf instance name of the instances. An error is generated if the specified name_patterns contain more than one level of hierarchy when the -of_nets option is used.

- -of_type *types*

  An optional switch and value pair that constrains the tool to return only instances whose type attribute is one of the following: design, cell, or primitive. The types value is either a single type string or a Tcl list of type strings such as {design cell}.

- -hierarchical

  An optional string that specifies to perform pattern matching relative to all instances found below the current design or below the specified instance_objects when the -below_of_instances option is specified. When this option is specified, the name_patterns argument cannot include slashes which are hierarchy separator symbols.

- -filter *attribute_equation*

  An optional switch and string that specify to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the instance object type. See section “Attribute Filtering Equation Syntax” on page 105 for more details on filtering attribute equation format.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument as a real regular expression instead of as a simple wildcard pattern. You must properly escape the bracket “[]” symbols so that they are interpreted as part of the regular expression and not interpreted by the Tcl shell. See section “Glob and Regular Expression Pattern Matching Syntax” on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for instances matching the name_patterns.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. However, it is possible the instance targeted by the name_patterns disappeared due to a change in a previous editing step. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

The following example returns a collection of all instances of cell types that start with ABC found anywhere below the current design.

get_instances ABC* -hierarchical -of_type cell

```
{u2/ABCD u1/u5/ABCDEF}
```

Example 2

The following example starts with the collection of all instances and filters it based on an attribute_equation of user-defined attributes.

get_instances -filter {myType1 || myType2 == "ABC"}

```
{u2 u1/u5}
```

Example 3

The following example starts with the collection of all instances and filters it based on the expression specified by the attribute_equation string.

get_instances -filter {name=~"u4*/u1*"}

```
{u4/u1 u4/u5/u1}
```

Example 4

In the following example, the collection of all instances matching a list of hierarchical name patterns are additionally filtered to only return instances of type design. The names u1/* and u*/u* are searched relative to the current design.

get_instances {u1/* u*/u*} -of_type design

```
{u4/u5}
```

Example 5

In the following example, the collection of all instances matching a leaf name pattern is returned. The leaf instance name u3* searches for all instances found below the current design.

get_instances u3* -hierarchical

```
{u3 u4/u3 u4/u5/u3 u5/u3}
```

Example 6

In the following example, the collection of all instances matching a leaf name pattern is returned. The leaf instance name u3* is matched against instances found below instance u4.

get_instances u3* -hierarchical -below_instances u4

```
{u4/u3 u4/u5/u3}
```

Example 7

In the following example, the *-parent_of_instances* option is used to find the parent instance of each instance on which a collection of pins exist. Only the parent instances whose leaf instance names match ABC* are returned. As described in the description of the -parent_of_instances switch, the optional name_pattern argument, in this case ABC*, is a string that is matched against the leaf instance name of every parent instance of the collection when the -parent_of_instances option is used.

set pin [get_pins]
get_instances ABC* -parent_of_instances [get_instances -of_pins $pin]

```
{u4/ABC1 u4/u5/ABC2}
```

Alternatively, you could use the base_name attribute of the pin objects and the parent_instance attribute of the instances to achieve the same result. However, the method used in this example is much more efficient because it deals with objects instead of strings containing object names. This method also avoids issues with string concatenation in the presence of escaped identifiers.

get_iproc_argument_default

Context: all contexts

Mode: all modes

Usage

get_iproc_argument_default ***proc_name arg_name*** [-exists] [-of_module *module_name*] [-silent]

Description

Returns the default value for the specified arg_name of the specified proc_name attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.

This command returns a null string when the specified argument has no default value. If you specify the -exists option, this command returns true if the specified argument has a default value and returns false when it does not.

Arguments

- ***proc_name***

  A required string that specifies the name of the iProc.

- ***arg_name***

  A required string that specifies the name of the argument.

- -exists

  An optional switch that changes the returned value of the command. When present, the command returns true when the specified argument has a default value and returns false when it does not. When not specified, the command returns the default value when it exists; otherwise it returns null.

- -of_module module_name

  An optional switch and value pair that constrains the command to return only the default value for the specified arg_name of the specified proc_name attached to the module specified by module_name.

- -silent

  An optional switch that specifies to suppress error messages if the specified proc_name, arg_name or module_name do not exist.

Return Value

If the -exist option is specified, this command returns true if the specified argument has a default value and returns false when it does not. If the -exist option is not specified, the command returns the default value when it exists; otherwise it returns null.

Example

The following example lists each argument attached to the P1 iProc on module mychip and lists its default value, if one exists; otherwise it reports the argument does not have a default value.

```
foreach arg [get_iproc_argument_list P1 -of_module mychip] {
        if {![get_iproc_argument_default P1 $arg -exist]} {
            puts "Argument $arg has no default value"
        } else {
            set def [get_iproc_argument_default P1 $arg]
            puts "Argument $arg has default value of $def"
        }
}
```

get_iproc_argument_list

Context: all contexts

Mode: all modes

Usage

get_iproc_argument_list ***iproc_name*** [-of_module *module_name*] [-silent]

Description

Returns the list of argument names for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.

Arguments

- ***iproc_name***

  A required string that specifies the name of the iProc for which the arguments are returned.

- -of_module module_name

  An optional switch and value pair that constrains the command to return only instances of iProcs attached to the module specified by module_name.

- -silent

  An optional switch that specifies to suppress error messages if the specified iProc or module do not exist.

Return Value

A Tcl list that contains the argument names of the specified iProc.

Example

The following example assigns the arguments attached to the chiptest iProc on module mychip to the variable chiptest_args:

```
set chiptest_args [get_iproc_argument_list chiptest -of_module mychip]
```

iProc
iProcsForModule

get_iproc_body

Context: all contexts

Mode: all modes

Usage

get_iproc_body ***iproc_name*** [-of_module *module_name*] [-silent]

Description

Returns the body for the specified iProc attached to the ICL module that was specified by the last iProcsForModule command, or to the ICL module specified by module_name.

Arguments

- ***iproc_name***

  A required string that specifies the name of the iProc.

- -of_module module_name

  An optional switch and value pair that constrains the command to return only the body of iProcs attached to the module specified by module_name.

- -silent

  An optional switch that specifies to suppress error messages if the specified iProc or module do not exist.

Return Value

None

Example

The following example returns the body of the chiptest iProc attached to module mychip:

```
get_iproc_body chiptest -of_module mychip
```

iProcsForModule

get_iproc_list

Context: all contexts

Mode: all modes

Usage

get_iproc_list [-of_module *module_name*] [-silent]

Description

Returns a Tcl list of iProcs attached to the ICL module specified by the last iProcsForModule command, or to the ICL module specified by module_name.

Arguments

- -of_module *module_name*

  An optional switch and value pair that constrains the command to return only instances of iProcs attached to the module specified by module_name.

- -silent

  An optional switch that specifies to suppress error messages if the specified module does not exist.

Return Value

A Tcl list of the iProc names, which are registered against the ICL module specified by the last iProcsForModule command or the ICL module specified by module_name.

Example

The following example assigns the list of iProcs attached to the mychip ICL module to the variable myprocs:

```
set myprocs [get_iproc_list -of_module mychip]
puts $myprocs
```

get_license_queue_timeout

Context: all contexts

Mode: all modes

Usage

get_license_queue_timeout

Description

Returns the amount of time Tessent Shell will queue for a required license as specified by the previous set_license_queue_timeout command, or its default value of “unlimited’ if the set_license_queue_timeout command was not issued or it was issued with that value.

The command may also return “no_queue” if that was specified by the set_license_queue_timeout command.

Arguments

- None

Example

The following example sets the license queue timeout value to 3 minutes, then displays the timeout value that was set:

```
SETUP> set_license_queue_timeout 3
SETUP> get_license_queue_timeout

3
```

Related Commands

set_license_queue_timeout

get_logical_library_list

Context: all contexts

Mode: all modes

Prerequisites: You must be in the -rtl context.

Usage

get_logical_library_list

Description

Returns a Tcl list with all logical design library names defined with the set_logical_design_libraries command.

This command and the concept of logical libraries is only available in the RTL mode.

This command is useful for writing scripts that operate on all libraries such as in Example3 of the get_modules command reference.

Arguments

- None

Return Value

A Tcl list with all logical design library names defined with the set_logical_library_list command.

Example

In the following example, the Tcl variable libs is defined by the result returned by the get_logical_library_list command. You can then use a foreach command to iterate on the list elements.

```
set libs [get_logical_library_list]
```

Related Commands

set_logical_design_libraries

get_module_parameter_list

Context: all contexts

Mode: all modes

Usage

get_module_parameter_list ***module_object*** [-overridden]

Description

Returns the list of parameters in a module.

This command is only available in -rtl mode (set_context dft -rtl). For more information, see the set_context command.

Arguments

- ***module_object***

  A required string that specifies the parameterized module objects whose parameters are to be returned.

- -overridden

  An optional switch that specifies to only list those parameters whose default values are overridden during an instantiation.

Return Value

List of parameters.

Example

In the following example, the get_module_parameter_list is used to obtain the list of parameters overridden in the specific instantiation.

```
set inst u1/myinst_i1
set params [get_module_parameter_list [get_attribute_value_list $inst\
                -name module_name] -overridden]
```

Related Commands

get_module_parameter_value

get_module_parameter_value

Context: all contexts

Mode: all modes

Usage

get_module_parameter_value ***parameter_name*** [-of_module *module_object*]

Description

Returns the value of the parameter on the specified module object.

This command is only available in -rtl mode (set_context dft -rtl). For more information, see the set_context command.

Arguments

- ***parameter_name***

  A required string that specifies the name of the parameter whose value is to be returned.

- -of_module *module_object*

  An optional switch and string pair that specifies the design module whose parameter value is to be returned. When omitted, the parameters of the current design are introspected.

Return Value

The value of the requested design module parameter.

Example

In the following example, the values of all overridden parameters are echoed in the transcript.

```
set inst [get_instance u1/myinst_i1]
set mod [get_attribute_value_list $inst -name module_name]
set params [get_module_parameter_list $mod -overridden]
foreach param $params {
        puts “parameter $param = [get_module_parameter_value $param \
            -of_mod $mod]”
}
```

Related Commands

get_module_parameter_list

get_modules

Context: all contexts

Mode: all modes

Usage

get_modules [*name_patterns*] [-of_type *type*] [-in_library *library*] [-vhdl_architecture *architecture*] [-of_instances *instance_objects*] [-below_instances *instance_objects*] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all modules that match the specified name_patterns list.

By default, this command returns all modules below the current design. You can use the -of_instances and -below_instances arguments to constrain the search. If no modules exist in memory, the command returns an empty collection.

You can have any number of wildcards or regular expressions in the name patterns.

In the rtl context, you may have more than one logical library. Because VHDL is also supported in the rtl context, you may also have multiple architectures. You define the list of available logical libraries using the set_logical_design_libraries command.

In the no_rtl context, only one library exists and is it named “work”.

The tool searches for the objects specified by the name_patterns argument in all libraries unless the -in_library option is specified. All other commands that have an option that refers to module names only search the default library. For example, you use the following command to create an instance of module M1 from library L1:

```
create_instance instance_name -of_module [get_module M1 -in_library L1]
```

In another example, an instance of module M1 from the default library is created because only the get_modules command knows how to look into other libraries.

```
create_instance instance_name -of_module M1
```

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to match the returned list of modules against. If no name_patterns are specified, the tool searches all modules.

- -of_type *type*

  An optional switch and value pair that constrains the command to return only modules of the specified types. The type is a single string or a Tcl list of stings matching one of the following values: design or cell.

- -in_library *library*

  An optional switch and value pair that specifies to restrict the search to a single library. The library value must be a single string corresponding to one of the logical library names defined with the set_logical_design_libraries command. When the -in_library option is not specified, all libraries are searched. This option is only allowed in the rtl context.

  Using -in_library XXX is equivalent to using -filter “library_name == XXX”

- -vhdl_architecture *architecture*

  An optional switch and value pair that specifies to restrict the search to a specific VHDL architecture name. This option is only useful when searching VHDL modules. When this option is not specified, one module per available architecture is returned. This option is only allowed in the rtl context.

  Using -vhdl_architecture XXX is equivalent to using -filter “vhdl_architecture == XXX”.

- -of_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only modules of the specified *instance_objects*. You could use the module_name attribute of the instance objects to perform a similar filtering but this method is more direct and efficient and automatically deals with libraries and architectures.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to return only modules corresponding to instances found below the specified *instance_objects*.

- -filter *attribute_equation*

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the module object type. See section “Attribute Filtering Equation Syntax” on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the name_patterns argument as a real regular expression instead of as a simple wildcard pattern. See section “Glob and Regular Expression Pattern Matching Syntax” on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for modules matching the name_patterns.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a

probable mistake when specifying patterns. However, it is possible the module targeted by the name_patterns disappeared due to a change in a previous editing step. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

The following example looks for modules whose name matches a* or b*.

get_modules {a* b*}

```
{ab abc b bcd}
```

Example 2

The following example looks for modules having one or two characters.

get_modules {[:alnum:]{1,2}} -regexp

```
{ab b}
```

Example 3

The following example gets the module object associated to an instance.

get_modules -of_instances u3/u5

```
{myModule}
```

Example 4

The following example looks for modules in all libraries and displays their names and language value in a tabular format.

```
set format_string "   "
append format_string "module_name = %-10s "
append format_string "language = %-10s "

set libs [get_logical_library_list]

foreach lib $libs {
   puts "Modules in library $lib are:"
   set mods [get_modules -in_library $lib]
   foreach_in_collection mod $mods {
   puts [format $format_string \
      [get_att_val $mod -name name]\
      [get_att_val $mod -name language]]
   }
}

// Command output:

Modules in library lib1 are:
   module_name = dut        language = verilog
Modules in library lib2 are:
   module_name = dut        language = verilog
Modules in library work are:
   module_name = top        language = verilog
```

Related Commands

create_module

get_multiprocessing_option

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion

Usage

get_multiprocessing_option { **-generic_delete | -generic_scheduler | -license_timeout | -lsf_heuristics | -lsf_learning | -lsf_options | -multithreading | -processors_per_grid_request | -remote_shell | -result_time_limit | -scheduler_timeout | -sge_options** }

Description

Returns the value of a single specified variable previously set with the set_multiprocessing_options command.

The get_multiprocessing_option command returns the value of a single multiprocessing variable that affects the behavior of the tool's built-in multiprocessing manager. These are values that you can set with the set_multiprocessing_options command. To display the values of multiprocessing variables in a human-readable format, use the report_multiprocessing_options command.

For more information about setting up for multiprocessing, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual* and "Using the Tessent Tcl Interface" in the *Tessent Shell User's Manual*.

Arguments

The arguments for the get_multiprocessing_option command are identical to those of the set_multiprocessing_options command, described on page 1840. For more information about the purpose of each switch, refer to the list of arguments there.

Example

The following example sets and then returns the value of the remote_shell variable:

```
> set_multiprocessing_options -remote_shell rsh
> puts [get_multiprocessing_option -remote_shell]

rsh
```

Related Commands

report_multiprocessing_options
report_processors
set_multiprocessing_options

get_name_list

Context: unspecified, all contexts

Mode: all modes

Usage

get_name_list ***object_spec*** [-remove_escaping] [-silent]

Description

Returns the name(s) of the specified object(s).

This command returns a list with the value of the name attribute for the objects specified by *object_spec*. Using this command is equivalent to executing the following command:

```
get_attribute_value_list object_spec -name name
```

The -remove_escaping argument removes the \ and the trailing spaces in an escaped identifier. Many legacy commands such as add_display_instance require the instance name to have the escape character stripped from its name. However, these legacy commands do accept collections as inputs in cases where the name format is not important. See examples below for an illustration of this behavior

If an object in *object_spec* does not exist, an error message displays unless the -silent switch is specified.

Arguments

- ***object_spec***

  A required string that specifies an object name, a Tcl list of object names, or a collection of objects.

- -remove_escaping

  An optional switch that specifies to strip out the \ and the trailing spaces in escaped identifiers. This option is useful to interact with legacy commands and the collection is not directly passed as input to them. See Example 2 for an illustration of this usage.

- -silent

  An optional switch that specifies to suppress error messages if an object in *object_spec* does not exist.

Example 1

The following example retrieves the names for a collection of pins.

get_name_list [get_pins u1/i*]

```
{u1/i1 u1/i2 u1/i3}
```

Example 2

The following example illustrates the use of the -remove_escaping option. In this example, you can see how legacy commands natively support collections as input arguments but do not support names with escaped identifiers.

Notice the use of the double set of braces when specifying a name pattern containing escape identifiers to get_pins. These braces are needed to prevent the Tcl shell from interpreting the \ character as its own escape sequence. You could also escape the \ using {u2/\\u1/u2 /p*} but using two sets of braces is easier when the pattern includes many slashes. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a complete description of pattern syntax and suggestions to use when the pattern is targeted for names containing escape characters.

get_pins {{u2/\u1/u2 /p*}}

```

get_nets

Context: all contexts

Mode: all modes

Usage

get_nets [*name_patterns*] [-below_instances *instance_objects*]
[-of_pins *pin_objects* |-of_ports *port_objects*]
[-hierarchical] [-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all hierarchical nets instantiated relative to the current design that match the specified name_patterns list, subject to filtering imposed by the other optional options.

When the name_patterns list is omitted, all nets are returned subject to filtering imposed by the other optional options.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of nets. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all nets. In Usage 2 described previously, the name patterns are not allowed to include slashes which are hierarchy separator symbols. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a complete description of the pattern syntax when the -regexp option is used and not used.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for nets below the specified instance_objects. Specified name_patterns are searched relative to the specified instance_objects when this option is used.

- -of_pins *pin_objects*

  An optional switch and value pair that constrains the command to return the net objects associated to the *pin objects*. Those are the nets having the exact same name as the pins and residing inside the instances on which the pins are on. For pins of cells, the inside nets corresponding to the pins are not visible and thus not returned. You cannot use a name_patterns list when using this option.To get the net connected to pins from the outside, use get_fanin and get_fanout -stop_on net.

- -of_ports *port_objects*

  An optional switch and value pair that constrains the command to return the net objects associated to the port_objects. Those are the nets having the exact same name as the ports and reside inside the current design. You cannot use a name_patterns list when using this option.

- -filter *attribute_equation*

  An optional switch and string that specify to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the net object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operators used simple wild card matching versus Posix extended regular expression based on the presence of the -regexp option or not.

- -regexp

  An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for nets matching the *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. However, it is possible the net targeted by the name_patterns disappeared due to a change in a previous editing step. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

In the following example, the collection of all nets is filtered based on an attribute_equation of user-defined attributes.

get_nets -filter {MyType1 || myType2 == "AB"}

```
{u3_Y u4_O2}
```

Example 2

In the following example, the collection of all nets matching a list of hierarchical name patterns are returned. The names u1/* and u*/u* are only searched relative to the current design. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for an example of pattern matching with regular expressions.

get_nets {u1/* u*/u*}

```
{u4/u4_Y u4/u1_Y u4/u2_Q u5/u4_Y u5/u1_Y u5/u2_Q}
```

Example 3

In the following example, the collection of all nets matching a leaf name pattern is returned. The leaf net name u4* searches for all nets found below the current design.

get_nets u4* -hierarchical

```
{u4_O1 u4_O2 u4_O3 u4/u4_Y u5/u4_Y}
```

get_open_pattern_set

Context: patterns -ijtag

Mode: analysis

Usage

get_open_pattern_set

Description

Returns the name of the currently open pattern set.

This command returns an empty string if no pattern set is open.

Arguments

- None

Return Value

The name of the currently open pattern set.

Example

The following example prints the name of the currently open pattern set:

```
puts "The curently opened pattern set is called [get_open_pattern_set]"
```

Related Commands

close_pattern_set
get_pattern_set_list
open_pattern_set
report_pattern_sets
reset_open_pattern_set

get_pattern_cycle_count

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Usage

get_pattern_cycle_count

Description

Reports the total number of cycles in the currently loaded WGL or STIL test pattern set.

The get_pattern_cycle_count command reports the total number of cycles in the currently loaded test pattern set. The test pattern set must be STIL or WGL format.

Example 1

The following example sets the pattern source to an external source, the *pat.wgl* file and displays the total number of cycles in the *pat.wgl* test pattern file:

```
read_patterns pat.wgl -wgl
get_pattern_cycle_count
```

Example 2

The following example sets the pattern source to an external pattern database source, the *pat1.wgl* file, appends the pat2.wgl test pattern file to it, and displays the total number of cycles contained in both test pattern files:

```
read_patterns pat1.wgl
read_patterns pat2.wgl –append
get_pattern_cycle_count   //reports total cycles for pat1 and pat2
```

Related Commands

read_patterns

get_pattern_set_data

Context: patterns -ijtag

Mode: analysis

Usage

get_pattern_set_data **pattern_set_name** [-unrolled] { -port_list | -event_list | -event_data *event_id* }

Description

Returns requested details of the internal representation of the specified pattern set.

The **get_pattern_set_data** command provides introspection into the internal representation of retargeted IJTAG patterns. Among other uses, this information can be used to generate pattern files for non-IJTAG compliant access mechanisms (for example, IEEE 1149.7), as long as the access hardware can produce the retargeted IJTAG patterns; that is, as long as the access mechanism does not put any restrictions on IJTAG retargeting.

Arguments

- pattern_set_name

  A required string that specifies the pattern set from which to introspect the requested information.

- -unrolled

  An optional switch that specifies to restrict the information returned when the -event_list or -event_data switches are used. The -unrolled switch has no effect on the -port_list switch. For more information on using -unrolled with -event_list and -event_data, refer to the descriptions of those switches below.

- -port_list

  An optional switch that specifies to return the list of ports to which values are written or from which values are read in the specified pattern set.

- -event_list

  An optional switch that specifies to return the list of all event identifiers of the pattern set.

  When the -event_list switch is used without the -unrolled switch, the returned list contains identifiers of events of type **vector**, **scan**, **reset**, **loop**, **goto_state** or **nop**.

  When the -event_list switch is used with the -unrolled switch, the returned list only contains identifiers of events of type **vector**, **loop** and **nop**. Events of type **scan**, **reset** and **goto_state** are unrolled or broken into the appropriate **vector** events.

  See "Event Types" below for details of all the event types.

- -event_data *event_id*

  An optional switch and string pair that specifies to return a list of key/value pairs of event data. *event_id* must be a string from the list returned by **get_pattern_set_data -event_list**.

You must first request the list of event identifiers from the pattern set, then you can use the event identifiers to get the pattern set data event by event.

Note

It is your responsibility to ensure that the -unrolled switch is used consistently. The event identifiers obtained by means of **get_pattern_set_data –event_list** only make sense in **get_pattern_set_data –event_data *event_id***, and the event identifiers obtained by means of **get_pattern_set_data –unrolled –event_list** only make sense in **get_pattern_set_data –unrolled –event_data *event_id***. As the event_ids are not guaranteed to be mutually exclusive, you must be careful to use –unrolled consistently.

The return value of **get_pattern_set_data pattern_set_name -event_data *event_id*** is always a list with an even number of elements, in which the first, third, fifth ... elements represent keys and the second, fourth, sixth ... elements represent values. This convention allows the conversion into an associative TCL array by means of the following command:

```
array set <variable name> <even-sized list>
```

TCL allows you to iterate on a list using several variables. This is useful to iterate on the results of **get_pattern_set_data**. For example, you can do the following:

```
foreach {key value} [get_pattern_set_data test -event_data] { … }
```

Some of the key/value pairs are guaranteed to appear in the result, others appear only if the related values exist in the retargeted patterns. The entries in the tables are flagged as “mandatory” or “optional” to reflect this.

Event Types

A **vector** event represents a single parallel vector, the stimulus data of the primary inputs (or bidirectional ports) of the design and the response data of primary outputs (or bidirectional ports).

A **scan** event represents one scan load/unload.

A **reset** event represents a global reset (like it would be invoked by e.g. applying a ‘0’ to the TRST port of a TAP controller).

A **loop** event represents a certain idle time. The **vector_count** in the event data refers to tester periods, potentially rounded towards the next integer.

A **goto_state** event represents the transition from one TAP state to another one. The paths for those transitions are the same as the default paths for TAP state transitions in SVF.

A **nop** event (“no operation”) represents the absence of any action. It is only required to hold the information about notes (iNotes) that have been added after the last actual action.

The type of the event can be derived from the identifier names. An event of type **vector** has an identifier named **vector *number***, where ***number*** is an increasing index. An event of type **scan** has an identifier named **scan *number*** and so on.

The following is an example of an event list:

```
{reset0 vector0 scan0 scan1 loop0 scan2 loop1 scan3 vector1}
```

Table 7-11. Events of type "vector"

Key	Value
port_values (mandatory)	String consisting of the characters 'U', 'D', '0', '1', 'X', 'Z', 'M', 'P' and '–'. The order is the same as in the port list (returned by get_pattern_set_data -port_list) The meaning of the characters is as follows: D expect 0 (hint: "down") U expect 1 (hint: "up") M expect Z (hint: "middle" or "median") X do not expect any specific value L drive 0 (hint: "low") H drive 1 (hint: "high") Z drive Z P pulse (only appears in combination with TCK) – ScanIn port during scan load D, U, X, L, H and Z are the same as in SVF. IJTAG adds P, M and – to the list of possible states
write_var.port_list (optional)	Names of the primary input ports (or bidirectional ports) which the write_var.name_list and write_var.inversion_list specifications refer to. Each port can occur only once
write_var.name_list (optional)	Names of iWriteVars associated with the ports. One element per port, same order as in the write_var.port_list
write_var.inversion_list (optional)	Specifies the inversion of the iWriteVars. The elements of the list can be 0 (no inversion) or 1 (inversion). The list must contain the same number of elements as the write_var.port_list
read_var.port_list (optional)	Names of the primary output ports (or bidirectional ports) which the read_var.name_list and read_var.inversion_list specifications refer to. Each port can occur several times, because an output port can be used to observe several targets at the same time
read_var.name_list (optional)	Names of iReadVars associated with the ports. One element per port, same order as in the read_var.port_list.
read_var.inversion_list (optional)	Specifies the inversion of the iReadVars. The elements of the list can be 0 (no inversion) or 1 (inversion). The list must contain the same number of elements as the read_var.port list

Table 7-11. Events of type “vector”

Key	Value
notes.text_list (optional)	List of notes preceding this event
notes.type_list (optional)	List of the types of the notes. The list has the same number of elements as notes.text_list. The elements can be either “user” or “process”. “user” notes are those which have been generated as a result of the iNote command. “process” notes are notes generated by the tool

Table 7-12. Events of type “scan”

Key	Value
port_values write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector” If the port_values contain expected values other than ‘X’, this indicates that the comparison must be done in each cycle of the scan load
scan_interface (mandatory)	Name of the scan interface (as specified in ICL)
scan_type (mandatory)	“DR” or “IR”. Always “DR” for designs without TAP
start_state (mandatory)	Start state of the TAP controller. Can be one of IDLE, DRPAUSE or IRPAUSE. For non-TAP designs, it can be IDLE or DRPAUSE. In this case, “DRPAUSE” means that there is no capture in this scan load, while “IDLE” means that there is a capture
end_state (mandatory)	End state of the TAP controller. Can be one of IDLE, DRPAUSE or IRPAUSE. For non-TAP designs, it can be IDLE or DRPAUSE. In this case, “DRPAUSE” means that there is no update in this scan load, while “IDLE” means that there is an update
chain_list (mandatory)	List of identifiers of active chains. If the active ScanInterface does not contain Chain statements, then the list consists of only one single element, which is called “default”
<chain_id>.length (mandatory)	Length of the scan chain

Table 7-12. Events of type “scan”

Key	Value
<chain_id>.offset (mandatory)	The number of overshift cycles, i.e. the difference between the number of shift cycles and the length of the chain
<chain_id>.inversion (mandatory)	The chain inversion between ScanInPort and ScanOutPort
<chain_id>.si_values (mandatory)	Scan-in value. A string consisting of ‘0’ and ‘1’ as wide as length+offset
<chain_id>.so_values (mandatory)	Scan-out value. A string consisting of ‘0’, ‘1’ and ‘X’ as wide as length+offset
<chain_id>.write_var.cycle_list (optional)	List of cycles which the <chain_id>.write_var.name_list and <chain_id>.write_var.inversion_list refer to
<chain_id>.write_var.name_list (optional)	List of iWriteVars, consistent with cycle_list, analogously defined as write_var.name_list
<chain_id>.write_var.inversion_list (optional)	List of inversions, consistent with cycle_list, analogously defined as write_var.inversion_list Note: the inversions take the scan-in inversions into account, such that it can be derived directly what has to be applied to the scan-in port
<chain_id>.read_var.cycle_list (optional)	List of cycles which the <chain_id>.read_var.name_list and <chain_id>.read_var.inversion_list refer to
<chain_id>.read_var.name_list (optional)	List of iReadVars, consistent with cycle_list, analogously defined as read_var.name_list
<chain_id>.read_var.inversion_list (optional)	List of inversions, consistent with cycle_list, analogously defined as read_var.inversion_list Note: the inversions take the scan-out inversions into account, such that it can be derived directly what has to be expected at the scan-out port
<chain_id>.register.name_list	The names of the ICL ScanRegisters in the correct order from scan-in to scan-out
<chain_id>.register.length_list	The list of register lengths in the order from scanin to scan-out. The elements in this list can be mapped uniquely to the elements in the list which is referenced by <chain_id>.register.name_list

Table 7-13. Events of type “reset”

Key	Value
notes.text_list notes.type_list	Same as in “vector”
sync (mandatory)	“On” or “Off”. Specifies whether a synchronous reset shall be enforced
type (mandatory)	“user” or “process”. “user” indicates the usage of iReset, whereas “process” indicates a reset generated by the tool, e.g. on behalf of the open_pattern_set command (if used without no_initial_ireset)

Table 7-14. Events of type “loop”

Key	Value
port_values write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector” If the port_values contain expected values other than ‘X’, this indicates that the comparison must be done in each cycle of the loop
vector_count (mandatory)	Duration in terms of tester periods, rounded towards the next integer

Table 7-15. Events of type “goto_state”

Key	Value
port_values write_var.port_list write_var.name_list write_var.inversion_list notes.text_list notes.type_list	Same as in “vector” If the port_values contain expected values other than ‘X’, this indicates that the comparison must be done in each cycle of the transition
start_state (mandatory)	IDLE, DRPAUSE or IRPAUSE
end_state (mandatory)	IDLE, DRPAUSE or IRPAUSE

Table 7-16. Events of type “nop”

Key	Value
notes.text_list notes.type_list	Same as in “vector”

Example

The following example illustrates the usage of the get_pattern_set_data command.

```

Related Commands

open_pattern_set

close_pattern_set

get_pattern_set_list

Context: patterns -ijtag

Mode: analysis

Usage

get_pattern_set_list

Description

Returns a Tcl list of all existing and closed pattern sets in the order of their creation.

The currently open pattern set is not part of the list.

Arguments

- None

Return Value

A Tcl list of all existing and closed pattern sets in the order of their creation.

Example

The following example sets the patlist variable to the set of all existing pattern sets.

```
set patlist [get_pattern_set_list]
```

Related Commands

close_pattern_set
get_open_pattern_set
open_pattern_set
report_pattern_sets
reset_open_pattern_set

get_pattern_set_option

Context: patterns -ijtag

Mode: analysis

Usage

get_pattern_set_option [pattern_set_name] {**-timeplate_name | -tester_period | -cycles | -tck_ratio | -initial_ireset | -active_scan_interfaces | -network_end_state | -tap_start_state | -tap_end_state | -saved**}

Description

Returns the value of the requested option for the specified pattern_set_name.

Arguments

- pattern_set_name

  Specifies an optional pattern set name from which to introspect the specified option. When not specified, the currently open pattern set is introspected.

- **-timeplate_name**

  Returns the name of the optional timeplate that was used when opening the pattern set. Returns null if the open_pattern_set -timeplate option was not specified; in this case the default timeplate is used. See open_pattern_set for a description of the default timeplate.

- **-tester_period**

  Returns the tester period used by the pattern set.

- **-cycles**

  Returns the complete number of tester cycles required to execute the pattern set on a tester.

- **-tck_ratio**

  Returns the tck_ratio value of the pattern set.

- **-initial_ireset**

  Returns 1 when the pattern set was opened without the -no_initial_ireset option; returns 0 when the option was used.

- **-active_scan_interfaces**

  Returns the names of the active scan interfaces.

- **-network_end_state**

  Returns keep, initial, or reset based on the value used with the close_pattern_set -network_end_state option.

- **-tap_start_state**

  Returns the expected TAP start state. The possible values are: “IDLE”, “DRPAUSE”, “IRPAUSE” or “any”.

- **-tap_end_state**

  Returns the established TAP end state. The possible values are: “IDLE”, “DRPAUSE”, or “IRPAUSE”. An error message is issued if you try to get the TAP end state of an open pattern set.

- **-saved**

  Returns 1 when the pattern set was written out using at least one write_patterns command. Returns 0 otherwise.

Return Value

The value of the requested option.

Example

In the following example, the total number of cycles for pattern set P1 is stored in the Tcl variable V1.

```
set V1 [get_pattern_set_option P1 -cycles]
```

Related Commands

open_pattern_set

close_pattern_set

get_pins

Context: all contexts

Mode: all modes

Usage

get_pins [name_patterns] [-of_instances *instance_objects* |
-below_instances *instance_objects* | -of_nets *net_objects* |
-of_gate_pin *gate_pin_objects*| -of_pseudo_ports *pseudo_port_objects*]
[-hierarchical] [-filter *attribute_equation*] [-direction input | output | inout]
[-regexp] [-nocase] [-silent]

Description

Returns a collection of all hierarchical pins instantiated relative to the current design that match the specified name_patterns list and subject to filtering imposed by the other optional options.

When the name_patterns list is omitted, all pins are returned subject to filtering imposed by the other optional options.

Arguments

- *name_patterns* | *leaf_instance/leaf_name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of pins. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all pins. The name patterns are not allowed to include more than one slash which is the hierarchy separator symbol. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a complete description of the pattern syntax when the -regexp option is used and not used.

  This argument cannot be specified with either the -of_nets or -of_gate_pin arguments.

- -of_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for pins on the specified *instance_objects*. When this option is specified, the optional name_patterns must be leaf_name patterns that are checked against the leaf name of the pins. An error is generated if the specified name_patterns contain more than one level of hierarchy when the -of_instances option is used. You could traverse the module_name attribute of the instance objects and look up the instantiated modules but this method is more direct and efficient and automatically deals with libraries and architectures.

- -below_instances *instance_objects*

  An optional switch and value pair that constrains the command to search for pins below the specified *instance_objects.* Specified name_patterns are searched relative to the specified *instance_objects* when this option is used.

- -of_nets *net_objects*

  An optional switch and value pair that constrains the command to return the pin objects associated to *net_objects*. Those are the pins having the exact same name as the nets and reside on the instances in which the nets are in. You cannot use a *name_patterns* list when using this option.

- -of_gate_pin *gate_pin_objects*

  An optional switch and value pair that constrains the command to return the pin objects associated to the specified *gate_pin_objects*. Given, a collection or list of gate_pin objects, the option is used to map the gate_pin object to the corresponding hierarchical pin objects. Any gate_pin object not having an associated hierarchical pin object is discarded. You cannot use a *name_patterns* list when using this option.

- -of_pseudo_ports *pseudo_port_objects*

  An optional switch and value pair that constrains the command to return the design pins associated with the specified pseudo-ports (user-added primary inputs or outputs).

- -hierarchical

  An optional string that specifies to perform pattern matching relative to all instances found below the current design. When this option is specified, the name_patterns argument cannot include more then one slash which are hierarchy separator symbols.

- -direction input | output | inout

  An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the pin object. When omitted, pins with any direction are considered.

- -filter *attribute_equation*

  An optional switch and string pair that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the pin object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operator use simple wildcard matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for pin names matching *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a

probable mistake when specifying patterns. However, it is possible the pin targeted by name_patterns disappeared due to a change in a previous editing step. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

In the following example, the collection of all pins is filtered based on an attribute_equation of user-defined attributes.

get_pins -filter {myType1 || myType2 == "ABC"}

```
{u1/Y u4/u4/A0 u7/D}
```

Example 2

In the following example, the collection of all pins matching a list of hierarchical name patterns is returned. The names u1/Y and u*/Q are only searched relative to the current design. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for examples of pattern matching with regular expressions.

get_pins {u1/Y u*/Q}

```
{u1/Y u2/Q u7/Q}
```

Example 3

In the following example, the pins with leaf_name matching Q* and found on instances of module DFF are returned

```
get_pins Q* -of_instances [get_instances -of_modules DFF]
{u2/reg1/Q u2/reg1/QB u3/reg5/Q}
```

Example 4

In the following example. the collection of all pins matching a leaf instance_name/leaf pin name pattern is returned. The tool searches for the leaf instance name u* in all instances found below the current design, and then searches for the leaf pin names matching Y* on those instances.

get_pins u*/Y* -hierarchical

```
{u1/Y u3/Y u4/u1/Y u4/u4/Y u4/u5/u1/Y u5/u1/Y u5/u3/Y u5/u4/Y u6/Y}
```

Example 5

This example return the pin names of the specified pseudo_port objects:

get_pins -of_pseudo_ports {user_pi1 user_pi2}

```
{u1/Y u3/Y u4/Y}
```

get_common_parent_instance
get_nets
get_icl_ports

get_ports

Context: all contexts

Mode: all modes

Usage

get_ports [*name_patterns*]
[-of_module *module_object* | -of_nets *net_objects* |
-of_pins *pin_objects* | -of_gate_pins *gate_pin_objects*]
[-direction input | output | inout]
[-of_type real | pseudo | all]
[-filter *attribute_equation*] [-regexp] [-nocase] [-silent]

Description

Returns a collection of all hierarchical ports on a given module that match the specified name_patterns list and subjected to filtering imposed by the other options.

You can have any number of wildcards or regular expressions in the name patterns.

Arguments

- *name_patterns*

  An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of ports. If no name_patterns are specified, the tool searches all ports.

- -of_module *module_object*

  An optional switch and value pair that constrains the command to return only the ports on the module specified by module_object. The module_object is a single module name, or a collection of one module object as returned by the get_modules command.

- -of_nets *net_objects*

  An optional switch and value pair that constrains the command to return the port objects associated to net_objects. These are the ports having the exact same name as the nets and residing on the current design. You cannot use a name_patterns list when using this option.

- -of_pins *pin_objects*

  An optional switch and value pair that constrains the command to return the ports defined on the modules that correspond to the pins specified by pin_objects.

  You can further constrain the command to return only Pseudo_ports or only real Ports using "-of_type pseudo | real"; if you do not specify the -of_type switch, by default, the tool returns all real ports (-of_type real). If you use this option in conjunction with "-of_type pseudo", the tool maps the pin that was added as part of the pseudo_port (user-added PI/PO) to the name of the associated pseudo_port. See Example 4. If you added a user-specified primary input or output (pseudo_port) without specifying the pin name using add_primary_inputs -pin_name, the name of the pseudo_port may not always match the

name of the pin specified; in this case, you can use this switch to find the name of the associated pseudo_port.

You cannot use this switch with the "-of_type all" option. You also cannot use this switch with a name_patterns list.

- -of_gate_pins *gate_pin_objects*

  An optional switch and value pair that constrains the command to return the ports on the current design associated to the gate_pin object. Any gate_pin object not associated to a port object on the current design is discarded. You cannot use a name_patterns list when using this option.

- -direction input | output | inout

  An optional switch and literal pair that specifies to filter results based on the value of the direction attribute on the port object. When omitted, ports with any direction are considered.

- -of_type real | pseudo | all

  An optional switch and literal pair that specifies to filter results based on the specified type of the port object. When omitted, only real design ports are considered. The option types have the following meaning:

  real — Only real design ports (Port object type) are included in the returned collection.

  pseudo — Only user-added pseudo ports (Pseudo_port object type) are included in the returned collection.

  all — Both real (design) and pseudo (user-added) ports are included in the returned collection.

- -filter *attribute_equation*

  An optional switch and string that specifies to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the port object type. See section "Attribute Filtering Equation Syntax" on page 105 for more details on filtering attribute equation format. The =~ and !~ matching operators use simple wild card matching versus Posix extended regular expression based on the presence of the -regexp option.

- -regexp

  An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a real regular expression instead of as a simple wildcard pattern. See section "Glob and Regular Expression Pattern Matching Syntax" on page 107 for a description of the regular expression syntax.

- -nocase

  An optional switch that directs the tool to perform case-insensitive pattern matching when looking for ports matching the *name_patterns*.

- -silent

  An optional switch that suppresses the warning message normally generated when the -filter argument returns an empty collection. The warning message is intended to indicate a probable mistake when specifying patterns. However, it is possible the module targeted by the name_patterns disappeared due to a change in a previous editing step. You can use the -silent switch to manage the case in which an empty collection is returned. This -silent option has no effect on any other error reporting.

Example 1

This example looks for ports on the current design whose name match I* or O*

get_ports {I* O*}

```
{I1 I2 I3 I4 I5 I6 I7 I8 O1 O2 O3}
```

Example 2

This example looks for scalar ports having one or two characters on module ModA.

get_ports {[[:alnum:]]{1,2}} -regexp -of_module ModA

```
{ab a b}
```

Example 3

This example return ports based on the option specified for the -of_type switch:

add_primary_input -internal inst1/Y inst1/Z -pin_name user_pi1
add_primary_input -internal inst2/Y -pin_name user_pi2
get_ports

```
{port1 port2 port3}
```

get_ports -of_type real

```
{port1 port2 port3}
```

get_ports -of_type pseudo

```
{user_pi1 user_pi2}
```

get_ports -of_type all

```
{port1 port2 port3 user_pi1 user_pi2}
```

get_pins -of_pseudo_ports user_pi1

```
{inst1/Y inst1/Z}
```

get_pins -of_pseudo_ports user_pi2

```
{inst2/Y}
```

get_pins -of_pseudo_ports {user_pi1 user_pi2}

```
{inst1/Y inst1/Z inst2/Y}
```

Example 4

This example returns the pseudo_ports associated with the user-specified primary inputs and primary outputs based on the option specified for the -of_type switch:

add_primary_input -internal inst1/Y inst1/Z -pin_name user_pi1
add_primary_input -internal inst2/Y

get_ports -of_pins inst1/Y

```
{Y}
```

get_ports -of_pins {inst1/Y inst1/Z} -of_type real

```
{Y Z}
```

get_ports -of_pins inst1/Y -of_type pseudo

```
{user_pi1}
```

get_ports -of_pins inst2/Y -of_type real

```
{Y}
```

get_ports -of_pins inst2/Y -of_type pseudo

```
{inst2/Y}
```

get_ports -of_pins {inst1/Y inst1/Z inst2/Y} -of_type pseudo

```
{user_pi1 user_pi1 inst2/Y}
```

get_procfile_name

Context: all contexts

Mode: all modes

Usage

get_procfile_name

Description

Returns the name of the procfile that was defined using the set_profile_name command.

Arguments

- None

Return Value

The name of the procfile as it was specified to the set_procfile_name command.

Example

In the following example, the path to the specified procfile name is stored in a Tcl variable.

```
set proc_file [get_procfile_name]
```

Related Commands

set_procfile_name

get_resource

Context: unspecified, all contexts

Mode: all modes

Usage

get_resource ***resource_list***

Description

Returns true when all resources in the specified resource_list are available.

You use this command inside your Tcl procs to check for the availability of resources and take appropriate action when they are missing. For example, you can choose to issue the create_flat_model command if your command depends on it and it is not yet available.

Arguments

- ***resource_list***

  A Tcl list of strings that contains any of the following resource names:

  design_is_elaborated

  Used to check that the hierarchical data model has been created using the set_current_design command.

  design_modules_exist

  Used to check that at least one Verilog or VHDL module exists in memory and can be accessed using the get_modules command.

  flat_model_exists

  Used to check that the flat data model is available. The flat data model was created by either the create_flat_model command or by the “set_system_mode analysis” command.

  icl_is_elaborated

  Used to check that the ICL hierarchical data model exists. It exists after the set_current_design command if an ICL module corresponding to the current design existed prior to issuing the command. It also exists in the analysis mode if the top-level ICL module was successfully extracted with ICL extract.

  icl_modules_exist

  Used to check that at least one ICL module exists in memory and can be accessed using the get_icl_modules command.

  rtl_mode_enabled

  Used to check that the -rtl option switch was used when specifying the context and that read-in Verilog and VHDL files can contain RTL constructs.

Example

The following example checks that both design and ICL modules exist.

```
if {![get_resource {design_modules_exist icl_modules_exist}]} {
   return -code error "you must first read in design and icl modules \
      before executing this command"
}
```

read_vhdl
set_context
set_current_design
set_system_mode

get_scratch_directory

Context: unspecified, all contexts

Mode: all modes

Usage

get_scratch_directory

Description

Returns the absolute path to the *scratch* directory.

The scratch directory is created in the temporary *.tessent.tmp* directory. The *.tessent.tmp* directory is created at tool invocation and deleted when the tool exits. The directory is created in the current working directory if write permissions are open; otherwise, it is created in */tmp*.

You can explicitly specify the location in which the *.tessent.tmp* directory is created by setting the TESSENT_TMP_LOCATION environment variable. If the location specified by this environment variable does not exist, is not a valid directory, or does not have write permission, the tool creates the *.tessent.tmp* directory in the default location which is the current working directory.

Arguments

None

Example

The following example displays the location of the scratch directory:

get_scratch_directory

```
/wv/dft/.tessent.tmp.rainbow.26857/scratch
```

get_simulation_context_list

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

get_simulation_context_list [-predefined | -user_defined]

Description

Returns the available simulation contexts in a Tcl list.

The get_simulation_context_list command returns all simulation contexts or returns only predefined or user-defined. If you issue the command without arguments, the command returns all simulation contexts. Note that for predefined simulation contexts, this command returns only the simulation contexts for which simulation data currently exists. This requires that the tool first read a procedure file.

Arguments

- -predefined

  An optional switch that specifies predefined simulation contexts, which are listed in Table 7-40 on page 1648.

- -user_defined

  An optional switch that specifies user-defined simulation contexts.

Example

The following example shows the Tcl list of values returned by the get_simulation_context_list command:

```
ANALYSIS> set_current_simulation_context stable_load_unload
ANALYSIS> add_simulation_context myContext1
ANALYSIS> add_simulation_context myContext2
ANALYSIS> get_simulation_context_list
{ stable_after_setup stable_load_unload stable_capture stable_shift myContext1 myContext2 }

ANALYSIS > get_simulation_context_list -user_defined
{  myContext1 myContext2 }

ANALYSIS > get_simulation_context_list -predefined
{ stable_after_setup stable_load_unload stable_capture stable_shift }
```

set_current_simulation_context

get_simulation_value_list

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Usage

get_simulation_value_list ***obj_spec***

Description

Returns a Tcl list of the simulation values on the specified gate_pin objects.

The get_simulation_value_list command returns the simulation values on the specified gate_pin objects in the current simulation context. The simulation value of a single gate_pin is either X, 0, 1, or Z.

Arguments

- ***obj_spec***

  A required value that specifies one or more gate_pin objects or pins that map to gate_pin objects (on library cell boundaries or preserved design boundaries).

Example

The following example shows that the get_simulation_value_list command is equivalent with querying the simulation_value attribute. However, note that get_attribute_value_list command requires a Tcl list of gate_pins in order to work correctly, as shown in the example:

```
> set_current_simulation_context stable_after_setup
> get_simulation_value_list {pi clk an_2/A0 an_2/Y}
1 X 1 X

> get_attribute_value_list [get_gate_pins {pi clk an_2/A0 an_2/Y}] -name simulation_value
1 X 1 X
```

Related Commands

add_simulation_force
delete_simulation_forces
report_simulation_forces

get_single_name

Context: unspecified, all contexts

Mode: all modes

Usage

get_single_name ***object_spec*** [-remove_escaping] [-silent]

Description

Returns a string with the name of the element specified by the object_spec argument.

The -remove_escaping argument removes the \ and the trailing spaces in an escaped identifier. Many legacy commands such as add_display_instance require the instance name to have the escape character stripped from its name. However, these legacy commands do accept collections as inputs in cases where the name format is not important. See the examples for an illustration of this behavior

If the object in *object_spec* does not exist, an error message displays unless the -silent switch is specified. If more than one object exists in object_spec, an error message displays unless the -silent switch is specified.

Arguments

- ***object_spec***

  A required string that specifies an object name or a single-element collection.

- -remove_escaping

  An optional switch that specifies to strip out the \ and the trailing spaces in escaped identifiers. This option is useful to interact with legacy commands and the collection is not directly passed as input to them. See Example 3 for an illustration of this usage.

- -silent

  An optional switch that specifies to suppress error messages if the object in *object_spec* does not exist.

Example 1

The following example prints out all of the modules in the database.

```
foreach_in_collection elem [get_modules] {
   puts "Module: [get_single_name $elem]"
}

Module: modb
Module: modc
Module: modd
Module: top
Module: GND
...
```

Example 2

The following example generates an error because the collection of pins returned by the get_pins commands contains more than one element.

get_single_name [get_pins u1/i*]

```
//  Error: Collection contains more than one element.
```

Example 3

The following example uses the -remove_escaping argument to strip out the slash "\" from an escaped identifier.

get_single_name {\x[0] } -remove_escaping

```
x[0]
```

get_system_mode

Context: unspecified, all contexts

Mode: all modes

Usage

get_system_mode [-previous]

Description

Returns the system mode.

Possible returned values are: setup, analysis, and insertion.

Arguments

- -previous

  An optional switch that specifies to return the previous system mode.

Example

The following example returns the current system mode and the previous system mode. This enables you to know that you came to the insertion mode through the analysis mode.

get_system_mode

```
insertion
```

get_system_mode -previous

```
analysis
```

Related Commands

set_system_mode

get_test_end_icall_list

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: all modes

Usage

get_test_end_icall_list

Description

Returns the iCalls added to the test_end procedure by the set_test_end_icall commands. Each iCall is a list containing the iProc and its arguments.

For each iCall added to the test_end procedure by the set_test_end_icall command, the get_test_end_icall_list command returns a list consisting of the three components that normally follow an iCall: the name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

Arguments

None

Example

The following example returns the iCalls added to the test_end procedure by the set_test_end_icall commands. Each iCall is a list consisting of the ICLinstance path, the name of the iProc, and the arguments to the iProc.

set_test_end_icall "m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on edt_bypass off"

set_test_end_icall "m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on edt_bypass off" -append

get_test_end_icall

```
{m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on edt_bypass off}
{m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on edt_bypass off}
```

get_tool_info

Context: unspecified, all contexts

Mode: all modes

Usage

get_tool_info -name | -version | -cpu_time [ms | s | m | h | d] |
-memory [b | kb | mb | gb] | -hostname

Description

Returns information about the current tool and the current run as a Tcl result.

You must specify exactly one switch.

Arguments

- -name

  A switch that specifies to return the name of the current tool.

- -version

  A switch that specifies to return the version of the current tool.

- -cpu_time [ms | s | m | h | d]

  A switch that specifies to return the user time of the process. By default, this command returns the time in seconds, but you can optionally specify one of the other units. The possible units are:

  ms — Specifies the time unit is milliseconds.

  s — Specifies the time unit is seconds.

  m — Specifies the time unit is minutes.

  h — Specifies the time unit is hours.

  d — Specifies the time unit is days.

- -memory [b | kb | mb | gb]

  A switch that specifies to return the memory usage. By default, this command returns the usage in bytes, but you can optionally specify one of the other units.

  b — Specifies the memory usage unit is bytes.

  kb — Specifies the memory usage unit is kilobytes.

  mb — Specifies the memory usage unit is megabytes.

  gb — Specifies the memory usage unit is gigabytes.

- -hostname

  A switch that specifies to return the hostname.

Example

The following examples return information about the current tool:

get_tool_info -name

```
tessent_shell
```

get_tool_info -version

```
2012.4
```

get_tool_info -cpu_time

```
2.773
```

get_tool_info -memory

```
228343808.0
```

get_tool_info -hostname

```
galactica
```

get_trace_flat_model_option

Context: all contexts

Mode: setup, analysis

Usage

get_trace_flat_model_option [-controllability] [-latch] [-tag_condition] [-stop_condition] [-stop_at_first_tag] [-max_levels] [-map_tag_to_design_module_boundary]

Description

Introspects the default behavior of the trace_flat_model command.

You can only specify one option at a time. The tool generates an error if more than one option is specified in a single command execution.

Arguments

- -controllability

  An optional switch that returns the current setting of the controllability option. Possible return values are:

  controlling— Gates are only traversed if the other inputs have simulated constant values making a single input directly controlling the output without an inversion.

  constant — Only pins with a constant value are traversed. This mode is useful to find the source of a constant value.

  unblocked — Gates are only traversed if the other inputs do not have simulated constant values making the input blocked from the output pin. Only unblocked combinational paths are traversed.

  connected—With this value, gates are always traversed when reached.

- -latch

  An optional switch that returns the current setting of the latch option. Possible return values are:

  normal — A latch is traced through only if the simulated value in stable_after_setup makes the latch satisfy the specified controllability requirements.

  transparent — All latches are traced through regardless of the value at the latch enable port.

- -tag_condition

  An optional switch that returns the current setting of the tag condition option. The returned value is an attribute expression. For more details about filtering attribute equation formats, refer to “Attribute Filtering Equation Syntax” on page 105.

- -stop_condition

  An optional switch that returns the stop condition for the trace. The returned value is an attribute expression.

- -stop_at_first_tag

  An optional switch that returns the current setting of the -stop_at_first_tag option. This option specifies whether to interrupt tracing when the first tag object with the specified controllability is found. Possible return values are: {ON | OFF}

- max_levels

  An optional switch that returns the current setting of the max_levels option. This option specifies the maximum level of gates to trace. Possible return values are: unlimited or a number.

- -map_tag_to_design_module_boundary

  An optional switch that returns the current setting of the map_tag_to_design_module_boundary option, which specifies whether to map the tag points to gate_pins outside of library cells. Possible return values are: {ON | OFF}

Example 1

The following example returns the current setting for the -controllability option.

```
get_trace_flat_model_option -controllability
```

Example 2

The following example returns the current setting for the -tag_condition option.

```
get_trace_flat_model_option -tag_condition
```

Example 3

The following example returns the current setting for -stop_condition option.

```
get_trace_flat_model_option -stop_condition
```

Example 4

The following example returns the current setting for the -stop_at_first_tag option.

```
get_trace_flat_model_option -stop_at_first_tag
```

Example 5

The following example returns the current setting for the -max_levels option.

```
get_trace_flat_model_option -max_levels
```

Example 6

The following example returns the current setting for the -latch option.

```
get_trace_flat_model_option -latch
```

set_trace_flat_model_options

trace_flat_model

get_transcript_style

Context: unspecified, all contexts

Mode: all modes

Usage

get_transcript_style

Description

Returns the keyword that specifies the style in which the tool transcripts commands.

The get_transcript_style command returns one of four keywords previously set with the set_transcript_style command. Possible return values are: off, full, tool_commands_only, and input_only.

Note that issuing the set_transcript_style command without an argument prints the style. Issuing get_transcript_style returns a value that you can assign to a variable for later use (see example below).

Arguments

None

Example

The following example stores the current transcript style in a variable, turns off transcripting, then later restores the original transcript style:

```
set old_transcript_style [get_transcript_style]
set_transcript_style off

... # do something with transcripting turned off

set_transcript_style $old_transcript_style
```

Related Commands

set_logfile_handling

set_transcript_style

get_tsdb_list

Context: all contexts

Mode: all modes

Usage

get_tsdb_list

Description

Returns a Tcl list of directory paths, relative to the current working directory, corresponding to all opened TSDB directories.

When the default or specified TSDB output directory is already created, it is returned in the list even if there was no explicit open_tsdb command for it.

Arguments

None

Examples

The following example shows the use of the get_tsdb_list command before and after closed some of them.

```
> get_tsdb_list
/home/projects/chipa/tsdbs/corea.tsdb /home/projects/chipa/tsdbs/coreb.t
sdb /home/projects/chipa/tsdbs/corec.tsdb
> close_tsdb [list ${tsdb_home}/corea.tsdb \
                   ${tsdb_home}/coreb.tsdb ]
> get_tsdb_list
/home/projects/chipa/tsdbs/corec.tsdb
```

Related Topics

open_tsdb

close_tsdb

set_tsdb_output_directory

get_tsdb_output_directory

get_tsdb_output_directory

Context: dft, patterns, unspecified

Mode: setup, analysis, insertion

Usage

get_tsdb_output_directory

Description

Returns the directory used by the process_dft_specification command which is the directory that has been previously set by the set_tsdb_output_directory command.

The TSDB output directory defaults to *./tsdb_outdir* until the set_tsdb_output_directory command has been invoked. When either the get_tsdb_output_directory or set_tsdb_output_directory command is invoked, the tool verifies that the specified path is a writable directory if it already exists, or that the parent directory is a writable directory if it is not.

The process_dft_specification command is currently the only command that makes use of the TSDB directory.

Arguments

None

Example 1

The following example stores the TSDB output directory into a Tcl variable called tsdb_outdir.

set tsdb_outdir [get_tsdb_output_directory]

Example 2

The following example shows a possible error than can be generated when invoking the command.

set_tsdb_output_directory dir1
exec “rm -r dir1; touch dir1”
get_tsdb_output_directory

```
//  Error: The specified tsdb_output_directory 'dir1' exists but is not a
directory.
//  Error: Directory was either deleted or its write permission changed
between now and the invokation of set_tsdb_output_directory command.
```

Related Commands

process_dft_specification

set_tsdb_output_directory

help

Context: unspecified, all contexts

Mode: all modes

Usage

help [*command_name*] [-manual] [-all]

Description

Lists commands and associated usage syntax.

Specifying the help command without any arguments returns a list of all available commands. Specifying a single command name displays its usage syntax.

Arguments

- *command_name*

  An optional string that specifies the name of the command for which you want help. Entering the first part of a command name returns a list of commands that start with the specified string. The *command_name* can include wildcard characters. For example, you can use an "*" to match zero or more characters at the position of the asterisk in the string.

  You also can use the tab completion method on available commands, which supplies missing characters between underscores. For example, specifying "help se_sy_m" and pressing the Tab key inserts "help set_system_mode" on the command line. Tab completion also works in this same way when invoking any tool command.

  If a single command is returned, its usage syntax also displays.

- -manual

  An optional switch that displays the reference manual description for the specified command. If you use this switch without specifying a command name, the tool opens the Tessent documentation system, giving you access to all the manuals for the product group.

- -all

  An optional switch that displays all command matches, including unavailable commands, which are identified with the "(...unavailable...)" notation. Specifying "help *unavailable_command_name*" displays the reason why a particular command is unavailable.

Example 1

The following example returns the usage syntax for the history command:

help history

```
history [ <count> ] [ -Nonumbers ] [ -Reverse ] [ -Save <savefile> ]
```

Example 2

The following example returns all commands in the current mode that begin with the string *set_design*:

help set_design

```
set_design_include_directories
set_design_macros
set_design_sources
```

Example 3

The following example returns all commands in the current mode that contain the string *design*:

help *design*

```
delete_design
get_current_design
set_current_design
set_design_include_directories
set_design_macros
set_design_sources
write_design
```

Example 4

The following example returns all commands containing the string *design*, including those that are unavailable:

help *design* -all

```
delete_design
find_design_names      (...unavailable...)
get_current_design
set_current_design
set_design_include_directories
set_design_macros
set_design_sources
write_design
```

history

Context: unspecified, all contexts

Mode: all modes

Usage

history [*list_count*] [-Nonumbers] [-Reverse] [-Save *filename*]

Description

Displays a list of previously executed commands.

You can use command line editing to recall a previous command and edit it for submission as a new command.

A leading number precedes each command line in the history list that indicates the order in which the commands were entered.

Arguments

- *list_count*

  An optional integer that specifies for the tool to display only the specified number (*list_count*) of most recent executed commands. If no *list_count* is specified, the tool displays all previously executed commands.

- -Nonumbers

  An optional string that specifies for the tool to display the history list without the leading numbers. This is useful for creating dofiles. The default displays the leading numbers.

- -Reverse

  An optional switch that specifies for the tool to display the history list starting with the most recent command rather than the oldest.

- -Save *filename*

  An optional switch and string pair that specifies the name of a file to which to write the command history. This is useful for creating dofiles.

Example 1

The following command saves the command history into a dofile for later execution.

history -save dofile1.txt

Example 2

The following command displays the history list with leading numbers, starting with the oldest command.

history

```
1  help hist
2  dof instructor/fault.do
```

```
 3  set_system_mode analysis
 4  set_fault_type stuck
 5  add_faults -all
 6  create_patterns
 7  report_statistics
 8  report_faults -class ATPG_UNTESTABLE
 9  analyze_fault /I$20/en -stuck_at 1
10  set_system_mode setup
11  set_system_mode analysis
12  set_fault_type iddq
13  add_faults -all
14  create_patterns
15  report_statistics
16  history
```

iApply

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iApply [-end_in_pause]

Description

Triggers the retargeting of all queued iRead and iWrite commands.

This command causes the retargeting engine to calculate the optimal sequence of scan loads, primary input stimulations, and primary output observations to satisfy all queued iRead targets and iWrite targets, as illustrated in Figure 7-15.

The number of parallel IO time frames and/or Scan time frames used to satisfy all queued up iWrite and iRead commands depends on the number of queued commands and the circuit topology described in the ICL description.

The solution criteria for the iWrite commands is that all specified iWrite values are achieved and present at the end of the iApply time frame. The order in which they become satisfied is unknown and is chosen by the solver in order to minimize the number of clock cycles needed to complete the tasks. The solver is designed to minimize transition on the writable objects and will limit them to a single transition per iApply time frame if the ICL circuit allows it.

If it is not possible to achieve all specified iWrite values at the end of the time frame, the specified iWrite command set is said to have no solution. The iRead object only needs to be observed once anywhere within the time frame. The value is strobed at the first opportunity that it becomes observable and is then ignored if re-observed on subsequent Scan or parallelIO time frames.

If there is no solution for the retargeting task, the iRead targets and iWrite targets are taken out of the queue and the current state of the circuit is retained. An error message appears in this case. If there is a solution, the solution is appended to the opened pattern set. The circuit state is updated to reflect the situation after the actions within the current iApply time frame have been applied.

You can use the optional -end_in_pause switch to help create IJTAG scan chain integrity tests. This switch allows you to observe the same values at the scan output that have been shifted in before. When you don’t use this switch, the shift register content is always overwritten by the capture values before being observed at the scan output.

Figure 7-15. iApply Time Frame

Arguments

- -end_in_pause

  An optional switch that helps you to create IJTAG scan chain integrity tests. The -end_in_pause switch changes the handling of the last scan load of the iApply and the first scan load of the next iApply.

  Note that the following explanation refers to states of a finite state machine (FSM) of a IEEE 1149.1 (JTAG) TAP controller. “IR” is instruction register, and “DR” is data register. For a complete explanation about how the TAP controller operates, refer to the IEEE 1149.1 standard document.

  When you use the -end_in_pause switch, and the last scan load is a “TAP scan load” (capture, shift and update activity is controlled by a TAP state machine), then the TAP state machine ends in the pause-DR or pause-IR state (that is, the tool performs no update-DR/update-IR). The first scan load of the next iApply starts from there and performs another scan load (obviously without capture-DR/capture-IR) before returning to RTI (run test/idle).

  When you use the -end_in_pause switch, and the last scan load is an ordinary scan load (capture, shift, and update activity is controlled by the appropriate CaptureEnPort, ShiftEnPort, UpdateEnPort), then the “update” of the last scan load of the iApply is skipped. The first scan load of the next iApply skips the “capture.” For more information about the CaptureEnPort, ShiftEnPort, UpdateEnPort keywords, refer to “ICL and PDL Modeling” in the *Tessent IJTAG User's Manual*.

  You can use this switch only when the iWrite targets are all part of ScanRegisters. Those ScanRegisters must be configurable to appear as one concatenated scan chain.

Return Value

None

Example 1

In the following example, two iWrite and two iRead commands are queued up when the iApply command is issued. The solver starts from the current state of the ICL circuit and looks for a series of ParallelIO and Scan time frames to have *u1.ina* equal to "*11*" and *u1.inb* equal to "*0*" at the end of the iApply time frame, and to have observed at least once the u1.out1 and u1.out2 objects.

The number of ParallelIO and Scan time frames needed to achieve the objective depends on the ICL network. If both *u1.ina* and *u1.inb* shared a common source in ICL, then the given PDL could not be satisfied because it would be impossible to have *u1.in1* high with *u1.inb* low together at the end of the iApply time frame.

```
iWrite u1.ina 0b11
iWrite u1.inb 0b0
iRead u1.out1
iRead u1.out2 0x7
iApply
```

Example 2

The following example applies a chain integrity test.

```
open_pattern_set chain_pattern
        iWrite myRegister 0b00110011
        iApply -end_in_pause
        iRead myRegister 0b00110011
        iApply
close_pattern_set
```

Related Commands

iRead iWrite

iCall

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iCall [icl_instance_path.]**iproc_name** [arguments …]

Description

Calls an iProc registered against the ICL module associated with the specified *effective_icl_instance_path*.

The *effective_icl_instance_path* is computed by concatenating the following three components:

iProc instance path — Path that exists when running commands specified within an iProc; it is set to the effective_icl_instance_path used in the iCall command that called the iProc. This value is empty when the iCall is not specified within an iProc.

iPrefix path — Path specified as the argument to the iPrefix command since the beginning of the open_pattern_set for commands that are not inside an iProc, or since the beginning of the iProc for commands that are inside an iProc. If no iPrefix command has yet been specified in the current scope, this value is empty.

icl_instance_path — An optional path specified in front of the iproc_name inside the iCall command, or in front of the icl_object inside other PDL commands such as iWrite, iRead, and iClock.

The effective_icl_instance_path is illustrated in the examples that follow.

The other arguments of this command are passed to the iProc in the same order as they appear in the command line. You must specify at least as many arguments as there are variables without default values in the corresponding iProc specification. For arguments defined with a default value in the associated iProc, their value takes on the default value when omitted.

Arguments

- [icl_instance_path.]**iproc_name**

  Name of an iProc preceded by an optional icl_instance_path and separated by a dot. The specified iProc must have been registered against the ICL module associated with the *effective_icl_instance_path*.

- arguments...

  Additional optional arguments that are passed to the iProc procedure. The number of required arguments depends on the definition of the iProc and on the existence of default values for the iProc arguments.

Return value

None. Unlike normal Tcl proc, even if the iProc contains the Tcl return command, the specified value is not returned by the iCall command which is consistent with the IJTAG 1687 standard.

Example

The following example assumes an ICL module called *myInstrument1* exists and this module is instantiated four times below the current design with the following instance paths:

core1_i1.myInst1_i1
core1_i1.myInst1_i2
core1_i2.myInst1_i1
core1_i2.myInst1_i2

The ICL module *myInstrument1* has a ICL sub-module called *myInstrument1_decode_logic* which is instantiated within *myInstrument1* as "*decode_logic*".

This numbered example illustrates the declarations of iProcs against the myInstrument1 and myInstrument_decode_logic modules, and the use of the iCall command to execute them against various instances of myInstrument1.

Line 1 issues the first iProcsForModule command for myInstrument1 which means iProcs declared afterward are registered against that module. For that reason, the iProcs declared at line 2 and 12 are registered against myInstrument1.

Line 24 issues the second iProcsForModule command which means the next iProcs are registered against the module myInstrument1_decode_logic.

The commands starting at line 41 are not inside an iProc so the iProc instance path value is empty when computing the effective_icl_instance_path for those commands.

The iCall on line 42 has an effective_icl_instance_path of core1_i1.myInst1_i1 because iPrefix path is currently set to core1_i1 (from the iPrefix command on line 41) and icl_instance_path is specified as myInst1_i1.

The iCall on line 42 specifies the value for the cnt argument while the second argument is left to the default value specified within the iProc declaration.

The iCall on line 43 overwrites the value of the second argument. Note that the first argument is required because it has no default values defined in the iProc declaration.

The iCall on line 5 is inside of an iProc, so it has an iProc instance path value that is equal to the effective_icl_instance_path value of the iCall that called the iProc. Looking at the iCall command on line 5 when called by the iCall on line 41, its effective_icl_instance_path is core1_i1.myInst1_i1.decode_logic because iProc instance path is core1_i1.myInst1_i1, iPrefix path is decode_logic, and icl_instance_path is empty.

The ICL instance core1_i1.myInst1_i1.decode_logic is an instance of ICL module myInstrument1_decode_logic and the proc Setup is registered against this module on line 25 because it follows the iProcsForModule command specified on line 24.

```
1  iProcsForModule myInstrument1
2  iProc run_testa {cnt {mode red}} {
3     iCall CheckStart
4     iPrefix decode_logic
5     iCall Setup $cnt $mode
6     iCall run $mode
7     iPrefix
8     iCall decode_logic.Status
10    iRead decode_logic.cnt $cnt
11 }
12 iProc CheckStart {} {
13    iRead go Fail
14    iRead done No
15    iApply
16 }
17 iProc run {mode} {
18    set cycles(red) 50
19    set cycles(blue) 90
20    set cycles(green) 70
21
22    iRunLoop $cycles($mode) -tck
23 }
24 iProcsForModule myInstrument1_decode_logic
25 iProc Setup { cnt mode } {
26    iWrite mode $mode
27    if {$mode == "red"} {
28       iWrite p1 0b0
29       iWrite p1(2) 0b1
30    }
31    iApply
32    iWrite enable Yes
33    iApply
34 }
35 iProc Status {} {
36    iRead done Yes
37    iRead go Pass
38    iRead count $cnt
39    iApply
40 }
41
41 iPrefix core1_i1
42 iCall myInst1_i1.run_testa 5
43 iCall myInst1_i2.run_testa 10 blue
44 iPrefix
45 iCall core1_i2.myInst1_i1.run_testa 15 red
```

Related Commands

iClock

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iClock [icl_instance_path.]icl_clock_port

Description

Checks whether a controlling clock path from a valid clock source to the specified clock port exists.

This command takes into account the iClockOverride specifications and the FreqMultiplier and FreqDivider properties in the ICL description.

Prior to issuing this command, clock path sensitization must have been performed using the appropriate iWrite and iApply commands such that *SelectedBy* sources of ICL ClockMultiplexers seen along the traced path have known constant values.

If clock tracing fails before reaching a primary input, an error is generated. If the primary input is reached but does not have an associated add_clocks command to specify the clock is active with a known period, an error is also generated.

The cumulative effective frequency multiplier is computed along the traced clock path and the final number is stored against the specified clock port. This value is later used to normalize the iRunLoop command to a common tester period as described in the iRunLoop command description.

Arguments

- icl_instance_path.]icl_clock_port

  Name of an internal or top-level clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The iCall command description describes how the effective_icl_instance_path value is computed and the factors that affect it.

Return Value

None

Example

In the following example, an iClock command is first specified to check that the reference source pin of the PLL has a controlling source to a primary input of the current design, and that the port has a specified clock period as defined by an add_clocks command.

The iWrite and iApply commands then program the PLL to a multiplication factor of 1.5 and set the clock multiplexer to the desired state.

The result of the PLL setup is reflected by the iClockOverride command such that the iClock definition on inst1.mbist_i1.clk, which traces to the PLL, properly computes the correct multiplication factor.

The first iRunLoop command specifies that the PLL will lock in less that 200 reference clock cycles. The second iRunLoop results in a loop of 4000 (6000*2/3) clock cycles at the current design boundary. For more information on the iRunLoop scaling algorithm, see the iRunLoop command description.

```
iClock inst1.pll.ref
iWrite inst1.pll_setup.mult 0b0100
iWrite inst1.pll_setup.source 0b01
iApply
iClockOverride inst1.pll.vco -freqMultiplier 3 -freqDivider 2
iRunLoop 200 -sck inst1.pll.ref
iClock inst1.mbist_i1.clk
iRunLoop 6000 -sck inst1.mbist_i1.clk
```

iClockOverride

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iClockOverride **[icl_instance_path.]icl_clock_port** -source [icl_instance_path.]icl_clock_source_port [-freqDivider divider] [-freqMultiplier multiplier]

iClockOverride **[icl_instance_path.]icl_clock_port** [-freqDivider divider] [-freqMultiplier multiplier]

Description

Models how the functional clocking has been programmed.

System clocking syntax inside ICL is adequate to describe a constant frequency multiplication and division number. With ClockMultiplexers in ICL, it is possible to model alternative sources as long as the select lines of the multiplexers are controlled by ijtag registers. The functional clocking path of ijtag instruments is not required to be controlled by ijtag itself. As long as the current functional clocking is properly modeled, the iRunLoop commands can be normalized correctly.

You should have a way to set up the functional clock using the ijtag network if you need to change it between patterns. You can use the complete syntax available inside the test_setup procedure to program an arbitrary functional clock system. You simply use this iClockOverride command to model how the functional clocking was programmed. Even if the multiplication factor is controlled by ijtag registers, you use the iClockOverride command to describe the effect of the newly written value. This is illustrated in the iClock command example.

You can use the iClockOverride command to override only the source, or only the cumulative multiplication/divider value, or both. If the -source option is not specified, the source is unchanged; it remains the source documented in ICL, or the last iClockOverride -source value that may have been specified within the current open pattern set.

If the -freqDivider and the-freqMultiplier arguments are both specified, both are overridden. Specifying just -freqDivider without -freqMultiplier or vice versa, sets the unspecified option to 1. If neither of the -freqDivider and the-freqMultiplier arguments are specified, the previous -freqDivider and the-freqMultiplier values are preserved, regardless of whether they came from ICL or a previously specified iClockOverride.

Arguments

- **[icl_instance_path.]icl_clock_port**

  A required value that specifies an internal clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The iCall command description describes how the effective_icl_instance_path value is computed and the factors that affect it.

- -source [icl_instance_path.]icl_clock_source_port

  An optional switch and value pair that specifies an internal or top-level clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The iCall command description describes how the effective_icl_instance_path value is computed and the factors that affect it.

- -freqDivider *divider*

  An optional option-value pair that overrides the frequency ratio between the *[icl_instance_path.]**icl_clock_port*** and its source. It's value defaults to 1 when -freqMultiplier is specified otherwise it defaults to the previously defined value, either from the definition in ICL or from a previous iClockOverride command on the given *[icl_instance_path.]**icl_clock_port***

- -freqMultiplier *divider*

  An optional option-value pair that overrides the frequency multiplication factor between the *[icl_instance_path.]**icl_clock_port*** and its source. It's value defaults to 1 when -freqDivider is specified otherwise it defaults to the previously defined value, either from the definition in ICL or from a previous iClockOverride command on the given *[icl_instance_path.]**icl_clock_port***

Return value

None

Example

The following example assumes both inst1.inst2.sysclock and clk2 are declared as ClockPorts in the ICL description. The first iClockOveride command only overrides the source and leaves the multiplication and division number unchanged. The second iClockOveride command overrides the frequency multiplication factor to 10 and the frequency division ratio to 1.

```
iClockOverride inst1.inst2.sysclock -source clk2
iClockOverride inst1.inst2.sysclock -freqMultiplication 10
```

identify_redundant_faults

Context: dft -edt, patterns -scan

Mode: analysis

Usage

identify_redundant_faults

Description

Identifies redundant faults among current faults whose redundancy has not yet been determined.

Note

By default, the create_patterns command automatically performs redundant fault identification at the conclusion of the run.

Identifies combinationally redundant (RE) faults from among those faults in the current fault list whose redundancy has not been determined yet.

This command is useful in situations where the tool has not specifically checked some faults for redundancy, but where establishing their redundancy might improve test coverage. The following are examples of such situations:

- When the tool generates patterns using named capture procedures, it does not identify RE faults. You might improve test coverage by using this command at the end of such an ATPG session.
- When the tool simulates external patterns, it does not identify RE faults among the undetected faults. You might improve test coverage by using this command after the simulation.

This command will only target faults not yet proven to be either RE or non-RE. For example, the command will not target a fault currently classified as det_simulation (DS) or that was classified as DS before but is now uncontrolled (UC) or unobserved (UO). The command is meaningful only when the current fault type is stuck-at, bridge, transition, or UDFM.

Example 1

The following example creates patterns using named capture procedures, then identifies the RE faults:

```
set_system_mode analysis
set_capture_procedures on -all
create_patterns

...
//  There may be unidentified redundant faults when generating patterns
//     with named capture procedures defined, which may lead to lower test
//     coverage being reported.
//  To perform redundant fault identification, invoke the command:
//     identify_redundant_faults
...
```

```

Example 2

The following example shows the command flow to identify the redundant faults after simulating external patterns that were created using named capture procedures:

set_system_mode analysis
read_patterns my_external_patt
simulate_patterns
identify_redundant_faults

Related Commands

create_patterns
report_statistics
simulate_patterns
set_capture_procedures
set_fault_type

iMerge

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iMerge {-begin [-error_on_conflict] | -end}

Description

Specifies the beginning and the end of a set of iCall commands that are meant to be processed in parallel, as much as possible, in the final representation of the test patterns.

iCall is the only PDL command which is allowed in between iMerge -begin and iMerge -end.

In the iProcs called by the iCalls, Tessent IJTAG identifies any resource conflicts, such as two PDL commands writing to the same register, and all conflicts arising from reservations done by means of the command iTake. All conflicting commands are then processed serially. For the remaining iCall commands, Tessent IJTAG tries to find an optimal parallel solution.

Arguments

- **-begin**

  A required switch that marks the beginning of the set of iCall commands to be processed in parallel.

- **-error_on_conflict**

  An optional switch that specifies to issue an error when there is a conflict rather than process the conflicting events serially. In the case of nested iMerge blocks, you only need to specify this switch on the outermost iMerge specification; the specification applies to all iMerge processes that are called from within the block.

  Refer to “iMerge Conflict Reporting” in the *Tessent IJTAG User’s Manual* for more information.

- **-end**

  A required switch that marks the end of the set of iCall commands to be processed in parallel.

Return value

None.

Example

```
iMerge -begin -error_on_conflict
iCall proc1
iCall proc2
iCall proc3
…
iMerge -end
```

iTake

import_dfm

Context: patterns -scan_diagnosis

Mode: analysis

Usage

import_dfm **-rdb** ***rdb_file*** **-layer** ***layer_name*** **-type** {**cell** | **open** | **bridge**}
[-sample *n*] [-replace]

Description

Imports a Calibre-compatible results database (RDB) file into a violations database (VDB).

The import_dfm command verifies that the DFM rule violations in the VDB match the layout geometries in the LDB. It then populates the VDB with the DFM rule violations.

Note

DFM shapes that fail verification are still imported into the VDB and used during annotation.

You must have previously opened the LDB and VDB with the open_layout command. Otherwise, Tessent Diagnosis issues an error message.

For more information, see "Diagnosis for Design for Manufacturability Analysis."

Arguments

- **-rdb** ***rdb_file***

  A required switch and string pair that specifies the Calibre-compatible DFM RDB file.

- **-layer** ***layer_name***

  A required switch and string pair that specifies the layer. You must specify a known layer in the layout-aware diagnosis layout file.

- **-type** {**cell** | **open** | **bridge**}

  A required switch and literal that specifies the type of DFM violation that you want to report.

- -sample *n*

  An optional switch and string pair that specifies a percentage value from 0 to 100. This value specifies the number of shapes that will be verified against the LDB. Setting this value to 0 prohibits verification.

  This switch has no effect on diagnosis. Use it to improve verification runtimes with the caveat that lowering the value decreases the verification accuracy.

- -replace

  An optional switch that specifies to remove from the VDB the DFM rule with the same rule name, and layer, and to replace it with the new RDB information.

Examples

The following example opens an LDB, creates the directory into which Tessent Diagnosis will write the VDB, and then imports the RDB files into the VDB created in the design.lddb directory. During the verification step, it verifies 10% of the rule violations in the VDB.

```
open_layout design.ldb design.lddb
import_dfm -rdb id_100.rdb -layer route_2 -type OPEN -sample 10 -replace
```

delete_dfm

index_collection

Context: unspecified, all contexts

Mode: all modes

Usage

index_collection ***collection index***

Description

Extracts a single object at a specified index in a collection and creates a new collection containing only that object.

The base collection remains unchanged.

Arguments

- ***collection***

  A required string that specifies the collection to be searched.

- ***index***

  A required integer that specifies the index into the collection. Allowed values are from 0 to *sizeof_collection* - 1.

Example

The following example shows the first and last object in a collection being extracted.

```
set c1 [get_instances {u1 u2 u3}]
{u1 u2 u3}

get_name_list [index_collection $c1 0]
u1

get_name_list [index_collection $c1 [expr [sizeof_collection $c1] -1 ]]
u3
```

iNote

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iNote **string**

Description

Inserts a note in the opened pattern set.

The note is attached to the time corresponding to where the iNote command is executed. When the pattern set is written to a pattern file by means of write_patterns commands, the note will appear as an annotation in the pattern file at the appropriate location. For simulation test benches, the note is displayed when the corresponding cycle to which the note is attached to is simulated.

Arguments

- **string**

  The comment string or note that will be added to the pattern set at the proper time. This must be a single normal Tcl string, Multiple words must be enclosed in quotes or braces.

Return value

None

Example

In the following example, the first iNote command is attached to the beginning of the pattern. The iNote string contains a variable that will be substituted before being sent to the iNote command. The second iNote command is attached to the time corresponding to the time reached to execute the previous iApply actions. The last iNote appears after the loop.

```
iNote "Setting up controller instance $inst"
iWrite mode blue; iApply
iNote “Running controller”
iWrite enable On; iApply
iRunLoop 30 -tck
iNote “Checking results”
iRead results pass; iApply
```

Related Commands

None

insert_test_logic

Context: dft -scan, dft -test_points

Mode: analysis

Prerequisites: To use the *-Verilog* switch, you must have defined a buffer model with the add_cell_models command or with a cell_type attribute.

Usage

Context: dft -test_points

insert_test_logic

Context: dft -scan

insert_test_logic [*filename* [-Fixed]] [-Scan {ON | OFf}] [-Test_point {ON | OFf}]
[-Ram {ON | OFf}] {[-UNlimited] | [-MAx_length *integer*] | [-NUmber [*integer*]]}
[-Clock {Nomerge | Merge}] [-Edge {Nomerge | Merge}]
[-COnnect {ON | OFf | Tied | Loop | Buffer}] [-Output {Share | New}]
[-MOdule {Norename | Rename}] [-Verilog] [-NEw_scan_po] [-Keep_original_net]

Description

Inserts the test structures you define into the netlist to increase the design's testability.

The tool inserts test structures into a design to increase the fault coverage (testability) of the design. Specifically, the tool attempts to increase a design's fault coverage with the insert_test_logic command by doing the following:

- Identifies sequential cells and replaces them with corresponding scan cells, and stitches them together into a scan chain. (Referred to as scan cell replacement and stitching.)
- Supports the adding of both system-defined and user-defined test points.
- Supports the automatic adding of test logic.

If you issue the insert_test_logic command after the set_wrapper_chains command, but have not issued the analyze_wrapper_cells command, you will get an error messsage stating that the wrapper chains analysis is required prior to insertion.

```
Error: Wrapper cells information is out of date:use
'analyze_wrapper_cells' to re-analyze wrapper cells prior to insertion.
```

For more information on scan replacement, test points, and test logic, refer to the *Tessent Tessent Scan and ATPG User's Manual*. For information on test point insertion, refer to "Manually Specifying Control and Observe Points" in the *Tessent Scan and ATPG User's Manual*. For information on handling pre-inserted scan cells, refer to "Specifying Existing Scan Cells" in the *Tessent Scan and ATPG User's Manual*.

Note

You can specify either a number chain specification or a maximum length chain specification in a single session among the insert_test_logic, add_scan_partition, and set_wrapper_chains commands, but, you cannot specify both. For example, if you specify the number of chains for input wrapper chains using the set_wrapper_chains -input_number option, you cannot use the insert_test_logic -max_length option for the remainder of the scan cells.

Arguments

- *filename* -Fixed

  An optional string and associated optional switch that specify the name of the ASCII file that lists the scan instances that you want the tool to stitch together. This file can contain information regarding scan cell ordering along with which instances are to be in each scan chain.

Note

If you use this file, it must contain all instances you want stitched. If you do not specify a filename, the tool stitches all non-scan cells that it has identified and mapped to scan cells into a scan chain using the settings of the other insert_test_logic arguments.

The -Fixed switch specifies for the tool to stitch the scan instances in the fixed order that is given in the filename. The default scan cell ordering is based on hierarchical rules, but within a hierarchical block the scan cell ordering is random. When using the -Fixed option, it also ignores certain scan input/output mapping performed by the add_scan_pins command.

For more information, refer to "Naming Scan Input and Output Ports" in the *Tessent Scan and ATPG User's Manual*.

The *filename* that you specify must list one instance per line and use the following format (all on one line):

```
instance_pathname cell_id chain_id [&sub_chain_name]
   [{+|-}[lockup_latch_model]]
```

instance_pathname — A string that specifies the name of the non-scan cell that you want the tool to put in the scan chain.

cell_id — An integer that specifies the placement of the instance_pathname in relation to other instance_pathnames. The tool places the instance having the smallest cell_id closest to the scan chain output. All instances in the same chain must have unique cell_ids.

chain_id — An integer that specifies the scan chain in which you want the tool to place the instance_pathname. The tool places instances with the same chain_id in the same chain.

&sub_chain_name — An optional special character and string that specifies the name of the sub-scan chain you defined with the add_sub_chains command. You need to

specify the subchain name when more than one subchain is defined for a sub-module or a hierarchical instance. No space is allowed between the ampersand (&) and the sub_chain_name argument.

{+|-}[*lockup_latch_model*] — An optional special character and an additional optional string that specifies the location of the lockup cell. The +|- argument specifies that a lockup cell is to be added to the scan out of the current instance_pathname. No space is allowed between the +|- and the lockup_latch_model name. Note that if you define a lockup cell in this file, you must specify every location that you want to insert lockup cells. If no lockup cells are defined in this file, the tool uses the settings in the set_lockup_cell and insert_test_logic commands. In such case, if you want the tool to automatically insert lockup cells in necessary locations, you should use the "-Clock/-Edge merge" option(s) with the insert_test_logic command. For more information on inserting lockup cells, refer to the set_lockup_cell command and "Merging Scan Chains with Different Shift Clocks" in the *Tessent Scan and ATPG User's Manual*.

+ — Specifies to use the clock used by the instance_pathname with the next lower cell_id. The next lower cell_id, refers to the a non-scan cell which will be connected to the scan out of the current *instance_pathname*.

- — Specifies to use the clock used by the *instance_pathname*.

lockup_latch_model — Specifies the name of the lockup cell model to use. The specified lockup cell must be defined by the add_cell_models command or defined in the ATPG library using the cell_type attribute. If the lockup_latch_model is not specified, the first model in the defined latch model list is used.

- -Scan ON | OFf

  An optional switch and literal pair that specifies whether the tool replaces the identified non-scan cells (scan candidates) with the corresponding scan cells. The valid literals are as follows:

  ON — A literal that enables the tool to replace the identified non-scan cells (scan candidates) with the corresponding scan cells. This is the default.

  OFf — A literal that disables the tool from replacing the identified non-scan cells (scan candidates) with the corresponding scan cells.

- -Test_point ON | OFf

  An optional switch and literal pair that specifies whether the tool adds the identified test logic and test points into the design. The valid literals are as follows:

  ON — A literal that enables the tool to add the identified test logic and test points into the design. This is the default.

  OFf — A literal that disables the tool from adding the identified test logic and test points into the design.

- -Ram ON | OFf

  An optional switch and literal pair that specifies whether the tool adds the identified test logic gates that are necessary to allow the ATPG tools access to the write control lines of the RAMs. The valid literals are as follows:

ON — A literal that enables the tool to add the identified test logic gates for RAM write control line access. This is the default.

OFf — A literal that disables the tool from adding the identified test logic gates for RAM write control line access.

- -UNlimited

  An optional switch specifying that the scan chain has no limit on the number of scan cells it contains. This is the default.

- -MAx_length *integer*

  An optional switch and integer pair that specifies the maximum number of scan cells that the tool can stitch into a scan chain. The tool evenly divides the scan cells into scan chains that are smaller than the max_length integer. Final results depend upon the number of scan candidates.

- -NUmber *integer*

  An optional switch and integer pair that specifies the exact number of scan chains that you want the tool to insert. Final results depend upon the number of scan candidates. The default number of chains is 1.

Note

The number of scan chains specified with insert_test_logic *-number* applies to the entire design. The number of scan chains specified with other commands such as set_wrapper_chains and add_scan_partition is subtracted from this number.

- -CLock Nomerge | Merge

  An optional switch and literal pair that specifies whether the tool uses different clocks on the same scan chain. The two valid literals are as follows:

  Nomerge — A literal that disables the use of different clocks on the same scan chain. This is the default.

  Merge — A literal that enables the use of different clocks on the same scan chain.

- -Edge Nomerge | Merge

  An optional switch and literal pair that specifies whether the tool merges stable high chains into stable low chains. The two valid literals are as follows:

  Nomerge — A literal that specifies to not merge stable high chains into stable low chains. This is the default.

  Merge — A literal that specifies to merge stable high chains into stable low chains.

- -COnnect ON | OFf | Tied | Loop | Buffer

  An optional switch and literal pair that specifies whether the tool stitches the scan cells together into a scan chain. The valid literals for stitching the scan chain are as follows:

ON — A literal that specifies for the tool to replace the identified non-scan cells with their corresponding scan replacements and to stitch those scan cells together into a scan chain. This is the default.

OFf — A literal that specifies for the tool to replace the identified non-scan cells with their corresponding scan replacements, but not stitch those scan cells together into scan chains.

Tied — A literal that specifies for the tool to replace the identified non-scan cells with their corresponding scan replacements, but not stitch those scan cells together into scan chains. This option has the tool tie the input/output scan pins to ground.

Loop — A literal that specifies for the tool to replace the identified non-scan cells with their corresponding scan replacements, but not stitch those scan cells together into scan chains. This option has the tool connect the scan_out pin to its own scan_in pin as a self-loop.

Buffer — A literal that specifies for the tool to replace the identified non-scan cells with their corresponding scan replacements, but not stitch those scan cells together into scan chains. This option has the tool connect the scan_out pin to its own scan_in pin as a self-loop with a buffer in between.

- -Output Share | New

  An optional switch and literal pair that specifies how the tool creates scan out ports on modules. The valid literals are as follows:

  Share — A literal specifying that the tool may use an existing module output port on modules for scan out, if that port is directly connected to the scan out of a scan cell. This is the default.

  New — A literal specifying that the tool should always create a new output port for scan out.

Note

If you want the tool to only create new scan output ports on the top-level module, use the *-NEw_scan_po* switch, instead of the *-Output* switch.

- -MOdule Norename | Rename

  An optional switch and literal pair that specifies how to name the modified module. The valid literals are as follows:

  Norename — A literal specifying that the tool should use the original module name, if it uses only one type of module modification, and that the original module is no longer used in the design. This is the default.

  Rename — A literal specifying that the tool should always rename a module if it modifies the module.

- -Verilog

  An optional switch that specifies to the tool that the final output netlist format will be Verilog, so that the tool knows to insert a buffer instance for any scan output pin in any module in the design hierarchy, if that pin also fans out as the module's functional output.

Without this switch, the tool uses the Verilog 'assign' statement to generate this scan output signal from the functional output. However, some layout tools do not support the Verilog assign statement, thus the -Verilog switch is required so that the tool will use a buffer instantiation and avoid using the assign statement.

Before using this command and switch, you must have defined a buffer model with the add_cell_models command or with a cell_type attribute.

- -NEw_scan_po

  An optional switch that specifies for the tool to create new scan primary output pins even though existing functional outputs are available to use as scan outputs. The switch is a special case of the -Output switch used with "New" literal, as it performs new scan output port creation only on the top-level module, instead of all modules.

- -Keep_original_net

  An optional switch that specifies for the tool to insert a buffer in the scan path, between the last scan cell at the top-level and the top-level scan output pin, when the scan cell output has no connection to top-level but has a functional connection to other logic. The buffer insertion is done to prevent renaming the original net that the scan cell is connected to the other logic with. When this switch is not specified, the tool renames the original net same as the primary output pin that it creates as scan output port.

Examples

The following example identifies the scannable sequential instances and then stitches them into scan chains when the insert_test_logic command executes:

```
add_clocks 0 clock
set_system_mode analysis
insert_test_logic -scan on -max_length 10
```

intercept_connection

Context: dft

Mode: insertion

Usage

intercept_connection **node -cell_function_name *function_name***
[-technology *dft_cell_selection_name*]
[-input2 *input2_source*] [-select *select_source*]
[-leaf_instance_prefix *prefix_name*]
[-only_when_has_functional_source]

Description

A command that uses the get_dft_cell command to obtain a cell with the specified function name and uses it to intercept a connection to a pin, port, or net.

This command performs interception inside both uniquified and not uniquified modules.

Arguments

- **node**

  A required value that is either a port, pin, or net name in the design or a collection of one port, pin, or net object. Based on the type of object and its direction attribute, in the case of a pin or a port, the source or destination connection of the object is intercepted. Table 7-17 shows the interception that is performed based on the node type. Note that an error is generated if the node is an inout pin or port, or if the node is a net corresponding to an inout pin or port.

Table 7-17. Interception based on node type

Node Type	Interception Done	Illustration
Input port	The node is a driver. The intercepting cell ends up between the input port and its original fanout.	

Table 7-17. Interception based on node type

Node Type	Interception Done	Illustration
Output port	The node is a sink. The intercepting cell ends up between the original fanin and the output port	Before and after interception:
Input pin	The node is a sink. The intercepting cell ends up between the original fanin and the input pin	Before and after interception:
Output pin	The node is a driver. The intercepting cell ends up between the output pin and its original fanout.	Before and after interception:

Table 7-17. Interception based on node type

Node Type	Interception Done	Illustration
Net corresponding to an input pin or an input port	The node is a driver. The intercepting cell ends up between the input pin or port and its original fanout.	Before and after interception:
Net corresponding to an output pin or an output port	The node is a sink. The intercepting cell ends up between the original fanin and the output pin or port.	Before and after interception:
Net not corresponding to a pin or a port	The node is a driver. The intercepting cell ends up between the driver of the net and its original fanout. Only single driver nets can be intercepted.	Before and after interception:

- **-cell_function_name *function_name***

  A required switch and string pair that specifies the function of the cell to be used for the interception. Table 7-18 shows the allowed cell function names and how the cell function affects the need to specify the -input2 and -select options.

Table 7-18. Allowed Cell Function Names

Function Name	Results
and	The interception is performed with the 2 input AND cell returned by the "get_dft_cell and" command. The -input2 option is required to specify the source of the second input. In the *Tessent Cell Library Manual*, see AND Cells for more details about the "and" cell_type and Cell Selection to know how to control which AND cell is used based on the specified -technology option.
buffer	The interception is performed with the BUFFER cell returned by the "get_dft_cell buffer" command. In the *Tessent Cell Library Manual*, see Buffer and Input Pad for more details about the "buffer" cell_type and Cell Selection to know how to control which BUFFER cell is used based on the specified -technology option.
inverter	The interception is performed with the INVERTER cell returned by the "get_dft_cell inverter" command. In the *Tessent Cell Library Manual*, see Inverter for more details about the "inverter" cell_type and Cell Selection to know how to control which INVERTER cell is used based on the specified -technology option.
mux	The interception is performed with the MUX cell returned by the "get_dft_cell mux" command. The -input2 and -select options are required to specify the source of the second data input and the select input. In the *Tessent Cell Library Manual*, see MUX Cell for more details about the "mux" cell_type and Cell Selection to know how to control which MUX cell is used based on the specified -technology option.
or	The interception is performed with the 2 input OR cell returned by the "get_dft_cell or" command. The -input2 option is required to specify the source of the second input. In the *Tessent Cell Library Manual*, see OR Gate for more details about the "or" cell_type and Cell Selection to know how to control which OR cell is used based on the specified -technology option.
clock_and	The interception is performed with the 2 input clock AND cell returned by the "get_dft_cell clock_and" command. The -input2 option is required to specify the source of the second input. In the *Tessent Cell Library Manual*, see AND Cells for more details about the "clock_and" cell_type and Cell Selection to know how to control which AND cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library. If one of the inputs has the function clock_in, it is selected for the interception.

Table 7-18. Allowed Cell Function Names

Function Name	Results
clock_buffer	The interception is performed with the clock BUFFER cell returned by the "get_dft_cell clock_buffer" command. In the *Tessent Cell Library Manual*, see Buffer and Input Pad for more details about the "clock_buffer" cell_type and Cell Selection to know how to control which BUFFER cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library.
clock_inverter	The interception is performed with the clock INVERTER cell returned by the "get_dft_cell clock_inverter" command. In the *Tessent Cell Library Manual*, see Inverter for more details about the "clock_inverter" cell_type and Cell Selection to know how to control which INVERTER cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library.
clock_mux	The interception is performed with the MUX cell returned by the "get_dft_cell clock_mux" command. The -input2 and -select options are required to specify the source of the second data input and the select input. In the *Tessent Cell Library Manual*, see MUX Cell for more details about the "clock_mux" cell_type and Cell Selection to know how to control which MUX cell is used based on the specified -technology option.
clock_or	The interception is performed with the 2 input clock OR cell returned by the "get_dft_cell clock_or" command. The -input2 option is required to specify the source of the second input. In the *Tessent Cell Library Manual*, see OR Gate for more details about the "clock_or" cell_type and Cell Selection to know how to control which OR cell is used based on the specified -technology option. The clock type is not learned and must be explicitly specified in the library. If one of the inputs has the function clock_in, it is selected for the interception.

- -technology *dft_cell_selection_name*

  An optional switch and value pair that specifies from which dft_cell_selection list the cell is to be used. You only need to specify this option if your library has more than one dft_cell_selection wrapper. If you have none, one is learned for the simple cell types, but you will not have access to the clock cells unless you have set their cell_type attribute in the library. See "Model-Level Attribute Descriptions" in the *Tessent Cell Library Manual* for information on how to specify the cell_type attribute.

- -input2 *input2_source*

  An optional switch that specifies a node to connect to the second input of the cell. The source must be a valid pin, port, or net object, or a name, or the constant value 0 or 1. You should use a constant value if you want to insert a gate now and then connect the extra pins

at some later time. Table 7-18 describes which values for -cell_function_name makes the specification of this option mandatory.

- -select *select_source*

  An optional switch and value pair that specifies a node to connect to the select input of the cell. The source must be a valid pin, port, or net object, or a name, or the constant value 0 or 1. You should use a constant value if you want to insert a gate now and then connect the extra pins at some later time. Table 7-18 describes which values for -cell_function_name make the specification of the -select option mandatory.

- -leaf_instance_prefix *prefix_name*

  This optional switch and value pair specifies the prefix to used when instantiating the cell. When this is not specified, the default is “insertion_”. The leaf instance name is constructed by concatenating the prefix_name with the cell_function_name. When a conflict is detected during instantiation, the tool automatically adds a “_<int>” suffix to uniquify the leaf name. You can use a specific prefix if you want to easily find the inserted cells in a synthesis or layout script by using a command such as “get_cells *prefix_name* -hier”.

- -only_when_has_functional_source

  This optional switch specifies to skip the instantiation of the cell and interception of the node when the attribute has_functional_source is 0 for the node. Instead, the node is disconnected and driven by the specified -input2 value. You cannot specify this option when -cell_function_name refers to a single input cell as there is no -input2 value to connect to in that case.

Example 1

The following example inserts a simple inverter gate by intercepting the existing connection between the u7/D pin and the u6/Y pin, shown on the left side of Figure 7-16. After the interception, the inverter A pin is connected to the u6/Y pin and the inverter Y pin is connected to the u7/D pin as shown on the right side of Figure 7-16.

INSERTION> intercept_connection u7/D -cell_function_name inverter

```
{insertion_inverter}
```

Figure 7-16. Inverter Interception

Example 2

The following example inserts a multiplexer and specifies to connect the second multiplexer input pin to 1, and to connect the multiplexer select pin to scan_en.

INSERTION> intercept_connection u4/u3/D -cell_function_name mux -input2 1 -select scan_en

```
{u4/insertion_mux_1}
```

This example does the same thing as first example above but specifies the -only_when_has_functional_source option. Because this option is specified, the tool connects the pin u1/u3/D directly to a constant 1 if its has_functional_source attribute evaluates to 0. In this case, the commands returns null as no intercepting cell was instantiated.

INSERTION> intercept_connection u4/u3/D -cell_function_name mux -input2 1 -select scan_en -only_when_has_functional_source

```
{}
```

Example 3

The following example script shows how to cascade three gates on a set of nodes. The example illustrates how the command is capable of handling non-unique designs. The script will work whether module “rep3” is uniquified or not. Notice how the example inserts the first gate level on all nets, and then adds two more levels in a row on each net. This illustrates that it does not matter if you insert all gate levels on each net or if you add one level at a time. In both cases, the result is identical.

Original design:

```
module ex (ina, outa, c1, c2, c3);

  input c1, c2, c3;
  input [3:0] ina;
  output [3:0] outa;

  rep3 rep3_0 (.ina(ina[0]), .outa(outa[0]));
  rep3 rep3_1 (.ina(ina[1]), .outa(outa[1]));
  rep3 rep3_2 (.ina(ina[2]), .outa(outa[2]));

  rep1 rep1 (.ina(ina[3]), .outa(outa[3]));

endmodule

module rep3 (ina, outa);
  input ina;
  output outa;

  assign outa = ina;

endmodule

module rep1 (ina, outa);
  input ina;
  output outa;
```

```
  assign outa = ina;

endmodule
```

The dofile:

```
set nets [get_nets -of_pins [get_pins -direction input]]
foreach_in_collection net $nets {
  intercept_connection $net -cell or -input2 c1}

foreach_in_collection net $nets {
  foreach var{2 3} {
   intercept_connection $net -cell [lindex {and or} [expr $l-2]] \
            -input2 c$var -leaf_inst_prefix myprefix_
  }
}
```

The modified design:

```
module ex (ina, outa, c1, c2, c3);

  input c1, c2, c3;
  input [3:0] ina;
  output [3:0] outa;

  rep3 rep3_0 (.ina(ina[0]), .outa(outa[0]), .c1(c1), .c2(c2), .c3(c3));
  rep3 rep3_1 (.ina(ina[1]), .outa(outa[1]), .c1(c1), .c2(c2), .c3(c3));
  rep3 rep3_2 (.ina(ina[2]), .outa(outa[2]), .c1(c1), .c2(c2), .c3(c3));

  rep1 rep1 (.ina(ina[3]), .outa(outa[3]), .c1(c1), .c2(c2), .c3(c3));

endmodule

module rep3 (ina, outa, c1, c2, c3);
  input ina;
  output outa;
  input c1, c2, c3;
  wire c1, c2, c3;

  wire ina_ts1, ina_ts2;

  OR210 insertion_or(.A(ina_ts1), .B(c1), .Y(outa));

  AN210 myprefix_and(.A(ina_ts2), .B(c2), .Y(ina_ts1));

  OR210 myprefix_or(.A(ina), .B(c3), .Y(ina_ts2));
endmodule

module rep1 (ina, outa, c1, c2, c3);
  input ina;
  output outa;
  input c1, c2, c3;
  wire c1, c2, c3;

  wire ina_ts1, ina_ts2;

  OR210 insertion_or(.A(ina_ts1), .B(c1), .Y(outa));
```

```
  AN210 myprefix_and(.A(ina_ts2), .B(c2), .Y(ina_ts1));

  OR210 myprefix_or(.A(ina), .B(c3), .Y(ina_ts2));
endmodule
```

Related Commands

get_dft_cell

iPrefix

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iPrefix [icl_instance_path]

Description

Sets the iPrefix path that is used to compute the effective_icl_instance_path for the iCall command and other PDL commands.

The effective_icl_instance_path is described in detail in the iCall command description.

This command is not affected by the previous iPrefix command. If the *icl_instance_path* argument is omitted, the iPrefix path value is set to empty. If the path is specified and the iPrefix command is *inside* an iProc, it must be a valid instance path relative to the current iProc instance path. If the path is specified and the iPrefix command is *not* inside an iProc, it must be a valid instance path relative to the current design.

Arguments

- icl_instance_path

  An optional string that defines the new value for iPrefix path used to compute the effective_icl_instance_path for the iCall command and other PDL commands such as the iRead, iWrite, and iClock commands.

Return Value

None

Example

In the following example, the iPrefix path value is first set to block1_i1.inst1_i1. It is then set to block1_i2 with the second invocation of the iPrefix command. Notice how the second iPrefix command completely replaces the value of the iPrefix path and is not influenced by the previous value of iPrefix path. Only the iCall, iClock, iRead, iWrite, iRunLoop, and iClockOverride commands are affected by the iPrefix command.

```
iPrefix block1_i1.inst1_i1
iWrite A 0b0
iPrefix block1_i2
iWrite inst1_i1.A 0b0
```

Related Commands

iProc

Context: all contexts

Mode: setup, analysis (patterns contexts only), insertion

Prerequisites: The iProcsForModule has been specified.

Usage

iProc **name variables body**

Description

Specifies a PDL procedure that can run later when referenced by the iCall command.

Analogously to the Tcl command "proc", the specification consists of the procedure name, the procedure variables, and the procedure body.

The specified procedure is registered against a specific ICL module that must have been previously loaded by read_icl and specified by iProcsForModule. Since the iProc is registered against a certain module, several iProcs with the same name may exist, each associated to a different ICL module. If an iProc is specified with a name that already exists for the current iProcsForModule, the new specification replaces the existing one. If an ICL module is deleted, the related iProcs are deleted too.

When the procedure is called using the iCall command, the variables in the argument list are substituted with the values specified in the iCall command. The commands inside the iProc body are executed in the scope of the instance against which the iProc is called.

Arguments

- **name**

  Name of the iProc which must be a simple scalar identifier. A simple scalar identifier starts with a letter and contains only letters, decimal digits, and underscores.

- **variables**

  A Tcl list of variable name or variable-value pairs enclosed in curly braces. The list of variables can contain either simple identifiers or identifier-value pairs, where the value specifies the default value of the variable. All simple identifiers must be in the list before the identifier-value pairs.

- **body**

  Commands to be executed when the procedure is called by means of the iCall command.

Return Value

None

Example

The following example shows an iProc called run_testa that is registered against the myInstrument1 ICL module. The iProc has two arguments: cnt and mode. The mode argument

is optional because it has a specified default value of “red”. The body of the iProc contains standard Tcl syntax and PDL commands. The cnt argument is specified before the mode argument because it has no specified default value.

```
iProcsForModule myInstrument1

iProc run_testa {cnt {mode red}} {
  set cycles(red) 50
  set cycles(blue) 90
  set cycles(green) 70

  iRead go Fail
  iRead done No
  iApply

  iWrite mode $mode
  if {$mode == "red"} {
    iWrite p1 0b0
    iWrite p1(2) 0b1
  }
  iApply

  iWrite enable Yes
  iApply

  iRunLoop $cycles($mode) -tck

  iRead done Yes
  iRead go Pass
  iRead count $cnt
  iApply
}
```

Related Commands

get_iproc_body
get_iproc_list
iCall
iProcsForModule

iProcsForModule

Context: all contexts

Mode: setup, analysis (patterns contexts only), insertion

Prerequisites: The corresponding ICL module already loaded.

Usage

iProcsForModule **icl_module_name [-iProcNameSpace** *name_space*]

Description

Specifies the ICL module for which subsequent iProc commands refer to.

An iProc is a PDL procedure written for a specific ICL module.

All references to ICL objects within the iProc refer to the instance path relative to the module it is written for. Once you have issued the iProcsForModule command, all iProcs defined afterward are registered against the specified ICL module. You cannot define any iProc until the iProcsForModule is set.

The iProcsForModule is specified once for each ICL module that you have iProcs to register against it. The iProcsForModule can only be specified for ICL modules that already have been loaded using the read_icl command.

To be sure that you load iProcs against the correct module, you can store all iProcs associated to a given ICL module inside a single file and add the proper iProcsForModule at the top of the file. With this organization, you can load the iProcs for any module as soon as the specified ICL module has been read in using the read_icl command.

Arguments

- **icl_module_name**

  Name of a valid ICL module which has already been loaded into memory using the read_icl command.

- **-iProcNameSpace** *name_space*

  An optional switch and string that creates a sub name space within each name space created from the ICL module name. When *name_space* is not specified, it defaults to the value set by the iUseProcNameSpace command.

Return Value

None

Example

In the following example, the file myCore.icl is read in; the file contains the entire ICL description of myCore. A child module of myCore is myInstrument1. The file *myInstrument1.iprocs* contains an iProcsForModule command that specifies that myProc defined afterward is meant to be registered against this module.

Sourcing the file myInstrument1.iprocs loads the iProcs defined in it. One of the instances of myInstrument1 within myCore is u2.u3. The iCall u2.u3.myProc command executes the iProc called *myProc* defined for module *myInstrument1* against the *u2.u3* ICL instance of that module. The solver will retarget the PDL found within that iProc to the boundary of myCore.

```
read_icl myCore.icl
source myInstrument1.iprocs

set_current_design myCore

set_system_mode analysis
open_pattern_set P1
iCall u2.u3.myProc
close_pattern_set
```

myInstrument1.iprocs file contains

```
iProcsForModule myInstrument1
iProc myProc {} {
   iRead u1.R 0b0
   iApply
}
```

iRead

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iRead **[icl_instance_path.]readable_icl_object** [value]

Description

Adds a read operation to the command queue that will be solved by the next iApply command.

You can specify an optional expected value to which the read value will be compared to when observed. The iApply command description describes how the iRead commands are interpreted by the iApply command.

Arguments

- **[icl_instance_path.]readable_icl_object**

  Specifies the ICL objects that are to be read. You can specify to add read operations for the following ICL objects: DataRegisters, ScanRegisters, DataOutPorts, DataInPorts, or an alias of any of these objects. The ICL objects must be found at the computed effective_icl_instance_path. The effective_icl_instance_path is described in detail in the iCall command description.

- value

  An optional constant number represented with Tcl binary, hexadecimal, or integer syntax or with a string corresponding to an enumeration symbol associated to the readable_icl_object in the ICL description.

Return Value

None

Example

The following example requests the readable_icl_objects *done* and *go* to be read and compared against the value represented by the enumeration symbol called *Yes* and *Pass* defined in ICL. The ICL object *count* is scheduled to be read but not compared to any expected value. The three requested read operations are solved when the iApply command executes.

```
iRead done Yes
iRead go Pass
iRead count
iRead status 0b1
iApply
```

iRelease

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iRelease *icl_resource*

Description

Releases the ownership of a resource that has been reserved by iTake.

Arguments

- *icl_resource*

  A required value that specifies the name of a register, a port or an instance. If an instance is specified, then all registers, ports and instances in *icl_resource* will be released.

Return value

None.

Example

```
iRelease RegA
iRelease InstA
```

Related Commands

iCall
iMerge
iTake

iReset

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iReset [-sync]

Description

Adds a sequence of actions to the current pattern set that is required to set the ICL network into the reset state.

The exact sequence performed depends on the presence of specific ports in the current design. Each ResetPort is pulsed high and each TRSTPort is pulsed low. If there are TMSPorts without a corresponding TRSTPort, TCK is pulsed five times with TMS held high followed by an extra pulse of TCK with TMS low.

After an iReset command, the entire ICL is in its reset state and the TAP finite state machines (when present) are in RunTestIdle state.

You should only use the iReset command once at the beginning of a pattern set. It is illegal to include an iReset inside an instrument PDL as its effect is global and destroys any ongoing action from all instruments. The iReset command is only allowed after open_pattern_set, in an iProc associated with the current design, or in test_setup/test_end procedures (the latter only allowed in contexts other than "patterns -ijtag"). Placing it inside an instrument-level iProc prevents this iProc from being iCalled from a higher level module.

If there is no explicit iReset at the beginning of an open pattern set, an iReset is implied unless the -no_initial_ireset option is used with the open_pattern_set command. Refer to the open_pattern_set command description to understand when and how the -no_initial_ireset option should be used.

Arguments

- -sync

An optional switch that forces a synchronous reset even if there are TRSTPorts in the current design. TCK is pulsed five times with TMS held high followed by an extra pulse of TCK with TMS low. If there is no TMS port, the -sync switch is ignored.

Return Value

None

Example

The following examples set the ICL network into the reset state:

```
iReset
iReset -sync
```

Related Commands

open_pattern_set

iRunLoop

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iRunLoop {count [-tck | -sck [icl_instance_path.]icl_clock_port]} | {-time *tvalue*}

Description

Creates a vector loop of a given duration.

In the generated pattern, the loop is converted into a loop of tester periods.

All clocks defined with the add_clocks commands toggle at their specified period in a free running fashion during the entire pattern. When using the -tck option, the iRunLoop count is expressed in terms of TCK periods and TCK is toggling during the loop. When the -sck [icl_instance_path.]icl_clock_port option is used, TCK is not toggling.

The specified [icl_instance_path.]icl_clock_port must have been specified in a prior iClock command such that its controlling source was verified and its effective cumulative multiplication factor computed. The size of the loop in the pattern depends on the computed effective multiplication factor as well as the ratio between the clock source period and the tester period. Table 7-19 outlines the resulting loop size in the generated pattern based on the various options.

Table 7-19. RunLoop Scaling Algorithm

Condition	Results
open_pattern_set -tck_ratio = 1 iRunLoop X -tck	TCK is defined with a pulsing waveform with the falling edge preceding the rising edge. The loop count is X and is over a single vector where TCK is set to pulse
open_pattern_set -tck_ratio = 2 iRunLoop X -tck	TCK is defined with a data waveform. The loop count is X and is over 2 vectors where TCK is low for the first vector and high for the second one
open_pattern_set -tck_ratio = 4, 8, 16,... iRunLoop X -tck	TCK is defined with a data waveform. The loop count is X and is over <tck_ratio> vectors where TCK is low for the first and last quarter of vectors and high for the middle ones.

Table 7-19. RunLoop Scaling Algorithm

Condition	Results
iRunLoop X -sck <clk> where <clk> has a source that was defined as an asynchronous clock using the add_clocks -period command	TCK is inactive during the loop. The loop count is Y and is over a single vector. Y = X / <effective multiplication factor> * (<async clock period>/<tester period>)
iRunLoop X -sck <clk> where <clk> has a source which was defined as a synchronous clock and the waveform defined for this clock has 2 edges	TCK is inactive during the loop. The loop count is Y and is over a single vector. Y = X / <effective multiplication factor>
iRunLoop X -sck <clk> where <clk> has a source that was defined as a synchronous clock and the waveform defined for this clock has 2*n edges	TCK is inactive during the loop. The loop count is Y and is over a single vector. Y = X / <effective multiplication factor>*1/n

Arguments

- **count**

  Required integer that specifies the number of clock cycles to be seen on TCK or on [icl_instance_path.]icl_clock_port. It is not required when the -time switch is used.

- -tck

  Optional switch that specifies that count refers to the test clock TCK.

- -sck [icl_instance_path.]icl_clock_port

  Optional switch and value pair that specifies for which clock pin the count is for. The value [icl_instance_path.]icl_clock_port specifies an internal or top-level clock port defined inside the ICL description. The specified clock port must be a port declared as a ClockPort or ToClockPort inside the ICL and it must be found at the computed effective_icl_instance_path. The effective_icl_instance_path is described in detail in the iCall command description. An iClock command on the [icl_instance_path.]icl_clock_port must have been issued prior to issuing the iRunLoop command.

- -time *tvalue*

  Optional switch and value pair that specifies a time delay *tvalue* instead of a cycle count. When TCK is OFF, iRunLoop -time is converted to a single vector loop, with a loop count of *tvalue*/tester_period rounded up to the next integer. If TCK is free running, TCK is ON and the loop count must be a multiple of the TCK ratio.

Return Value

None

Example 1

The following example specifies a run loop of 10000 tck period. The tck clock is toggling during the loop when the iRunLoop command is using the -tck option.

```
iRunLoop 10000 -tck
```

Example 2

The following example specifies a run loop of a 1000 system clock cycles on the clk pin of the u1 instance. The iClock command checks that the clock port is controlled by a valid source and computes the cumulative multiplication factor between the primary input and the clock port. The run loop is automatically adjusted such that the u1.clk port receives a minimum of 1000 cycles at the u1 instance. The TCK port may or may not be toggling.

```
iClock u1.clk
iRunLoop 1000 -sck u1.clk
```

Example 3

The following examples specify run loops that must last for at least the specified time.

```
iRunLoop -time 2000ns
iRunLoop -time 4.56E+2ns
iRunLoop -time 5.67E-1us
```

report_clocks

is_collection

Context: unspecified, all contexts

Mode: all modes

Usage

is_collection **string** [-with_object *obj_type*] [-single_type_objects]

Description

Indicates whether string is a collection handle.

This command returns true if the provided string is a collection handle. You use this command inside a Tcl proc to check if the passed in argument is a collection of objects versus names of objects. See the example below for an example usage.

You can also use this command to check if the collection contains only one type of objects or objects of a specific type.

Arguments

- string

  A required string that specifies the collection whose existence is to be verified. This command returns true if the collection exists.

- -with_object *obj_type*

  An optional switch and string that specifies whether the collection specified by string contains at least one object of the type specified by obj_type. This command returns true if at least one object of the type specified by obj_type exists.

- -single_type_objects

  An optional switch that specifies whether the collection specified by string contains objects of all the same type. This command return true only if all objects are of the same type.

Example

The following example uses the is_collection command to verify that the net argument is already a collection of nets and, if not, the get_nets command is used to create the collection of nets assuming <net> is instead a Tcl list of net names. If the passed-in argument is a collection, it is checked to verify that it only contain net objects. With this code, the proc myProc can be

invoked with either a Tcl list of names of nets, or a collection of nets and the proc automatically adapts.

```
proc myProc {net} {
   if {[is_collection $net]} {
       if {![is_collection $net -with_object net -single_type_objects]} {
           return -code error "<net> contains other object types than net"
       }
   } else {
       set net [get_nets $net]
   }
   #$net is definitely a collection of nets
   ...
}
```

iTake

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iTake *icl_resource*

Description

Used inside of an iProc to reserve a resource (a port, a register or an instance) for exclusive use with this iProc.

No other parallel running iProcs are allowed to alter states or clock frequencies on the resources taken by an iProc. The reservation persists until the end of the iProc.

Arguments

- *icl_resource*

  A required value that specifies the name of a register, a port or an instance. If an instance is specified, then all registers, ports and instances in *icl_resource* will be taken.

Return value

None.

Example

```
iTake RegA
iTake InstA
```

Related Commands

iUseProcNameSpace

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iUseProcNameSpace [*name_space*]

Description

Specifies a name space that is used for all subsequent iCalls made within the iProc in which the iUseProcNameSpace command appears.

The scope of this command is limited to within the iProc in which it appears. Invoking this command a second time within the same iProc changes the name space to the new value of *name_space*.

If iUseProcNameSpace is invoked without the *name_space* argument, the name space is set to that of the root module.

Arguments

- *name_space*

  An optional string that specifies the name space.

  The name space name must be formed from an initial upper or lower case alphabetic character followed by an optional sequence of upper or lower case alphanumeric or underscore characters ([a-zA-Z][a-zA-Z0-9_]*).

Return Value

None

Example

```
iUseProcNameSpace MyNameSpace //set namespace to MyNameSpace
iUseProcNameSpace // return to root name space
```

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the “patterns -ijtag context”, to use this command you must have previously opened a pattern set with the open_pattern_set command.
In the “dft”, “patterns –scan” and “patterns -scan_retargeting” context, you can use this command only as part of an iProc that is called during the processing of a procfile. For more information, see “IJTAG and ATPG in Tessent Shell” in the *Tessent IJTAG User's Manual*.

Usage

iWrite **[icl_instance_path.]writable_icl_object** value

Description

Adds a write operation to the command queue that will be solved by the next iApply command.

The ICL objects that can be written are DataRegisters, ScanRegisters, DataOutPorts, DataInPorts or an alias of any of these objects. A value to be written must be specified as the second argument. How the iWrite commands are interpreted by the iApply command is described in the iApply command description.

Arguments

- **[icl_instance_path.]writable_icl_object**

  Specifies the ICL objects that are to be written. You can specify to add write operations for the following ICL objects: DataRegisters, ScanRegisters, DataOutPorts, DataInPorts, or an alias of any of these objects. The ICL objects must be found at the computed effective_icl_instance_path. The effective_icl_instance_path is described in detail in the iCall command description.

- value

  An optional constant number represented with Tcl binary, hexadecimal, or integer syntax or with a string corresponding to an enumeration symbol associated to the written objects in the ICL description.

Return Value

None

Example

The following example requests the writable_icl_object mode to be written with the value represented by the enumeration symbol *goNogo* defined in ICL. The two requested write operations are solved when the iApply command is executed.

```
iWrite mode goNogo

launch_sid_tester

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Usage

launch_sid_tester **-cdp** ***cdp_path*** [-new]

Arguments

- **-cdp** ***cpd_path***

  A required switch and string pair that specifies a CDP.

- **-new**

  An optional switch that specifies to create a new CDP at the location specified by the -cdp switch. By default, the tool opens an existing CDP.

Description

Directs Tessent Shell to launch the SID tester process on a local host using the selected_tester and the port number as specified in the configuration data file. Additionally, this command specifies an existing CDP or initializes a new CDP.

During the launch, Tessent Shell passes the hardware and pin map configuration data to the SID tester so that the SID tester can perform the proper setup tasks.

You must have loaded the configuration data file with the read_config_data command prior to running this command.

Note

SVF-based CDPs are configured with asynchronous clocking. The tool does not provide clock waveforms to the DUT, therefore you must source the appropriate clocks yourself.

Note

You can only work with one SID tester at a time. To launch a new SID tester you must first shutdown the current SID tester with the shutdown_sid_tester command.

Example

The following example initializes a new CDP named “cdp1” and launches the SID tester process.

```
launch_sid_tester -cdp ./cdp1 -new
```

Refer to “Executing an IJTAG Test Pattern” in *Tessent SiliconInsight User’s Manual for Tessent Shell* for a sample usage scenario.

shutdown_sid_tester

lock_current_registration

Context: unspecified, all contexts

Mode: all modes

Usage

lock_current_registration

Description

Locks all previously registered commands and attributes preventing them from being unregistered and modified.

After you verified that your registered commands and/or attributes work correctly, you can make them into a *plugin* that Tessent Shell automatically loads during initialization. Simply place your files in a directory called <plugin_dir>/tcl_modules/<my_dir> where <plugin_dir> and <my_dir> are arbitrary directory names. Set the TESSENT_PLUGIN_PATH environment variable to point to the <plugin_dir> directory and any files with a .tcl extension found inside <plugin_dir>/tcl_modules/<my_dir> will be evaluated into the Tcl namespace ::tcl_modules::<my_dir>. Just like the PATH environment variable, you can specify more that one search location by separating multiple directory namies with a colon.

If you name your <plugin_dir> directory name “tessent_plugin” and place it one level above the bin directory of Tessent Shell, it will be automatically loaded unless the environment variable TESSENT_PLUGIN_IGNORE_DEFAULT_PATH is defined. Once the plugins are loaded, the command lock_current_registration is issued so that they cannot be unregistered accidently.

Arguments

- **None**

Example

The following example registers a string attribute called myAtt for the object type pin and then issues a lock_current_registration command to make it impossible to unregister the attribute.

```
register_attribute -name myAtt -value_type string -object_type pin
lock_current_registrations
```

[-SKIP_PATterns *num_to_skip*] [-FIRST_OBS_pattern]

or

macrotest {{***ID#*** | ***pin_pathname*** | ***instance_name***} ***pattern_filename***}
[-L_H | -NO_L_H] [-VARY_observe_by_pattern] [-VERBose | -NO_VERBose]
[-VERIfy | -NO_VERIfy] [-MASK_nonobservation_sites]
[-NO_FIll_patterns] [-TE_observation_only | -LE_observation_only]
[-NO_REPOrt_observation_candidates | -REPOrt_observation_candidates]
[-FAILure_analysis] [-EXHAUSTIvely_search]
[-SKIP_PATterns *num_to_skip*] [-FIRST_OBS_pattern]

Description

Runs the MacroTest utility to automatically generate manufacturing test patterns for embedded logic and memories referred to as macros. This utility is useful for applying specific patterns that test the insides of a macro, thereby improving overall IC test quality.

Note

Although a macro is typically embedded logic or a memory, it can also be a disjoint set of internal sites or a single block of hardware represented by an instance in HDL.

MacroTest reads patterns from the text file you provide and converts them into scan-based manufacturing test patterns. These test patterns, when applied to the chip, deliver the underlying patterns to the appropriate embedded location through intervening logic. The following is a brief summary of the capabilities of MacroTest:

- Reduces overall test generation time
- Has no impact on area or performance
- Enables you to test multiple macros in parallel
- Supports user-selected scan observation points
- Allows you to define macro output values that do not require observation

- Supports synchronous memories; for example, supports positive (or negative) edge-triggered memories embedded between positive (or negative) edge-triggered scan chains
- Analyzes single macros, and report patterns that are logically inconsistent with the surrounding hardware
- Fault grades the logic surrounding the macro

As a special form of the run command, the macrotest command uses all existing ATPG and cell constraints and limits. By default, if you have added faults, the macrotest command randomly fills bits that are unnecessary for testing the macro and fault simulates. This is recommended so you can observe the pattern conversion progression. You can always issue the reset_state command after the macrotest run to revert to no coverage due to the MacroTest patterns.

Note

To obtain a high degree of precision for resolving any conversion problems, MacroTest fault simulates one pattern at a time, rather than 32 at a time.

The observability of some patterns may not be verified. Pin(s) and pattern are reported and whether or not observability was verified, and then processing stops. Typically, this is because a scan chain clock and an input on the macro are shared. Also, pulsing the macro pin pulses the scan clock, causing the scan cells to update, making the observability invalid. In such cases, specify a sequential MacroTest pattern such that you specify the macro input values to read, including a pulse of the shared clock, in the first cycle of the pattern. Specify the known output values in the second cycle. MacroTest uses the sequential engine for such patterns, allowing a full cycle for the values to come out of the macro and propagate to the scan cells where they will be captured. Such operation of a shared clock should let you verify the macro's observability.

If the macro being tested is a RAM, the MacroTest patterns might perform several writes followed by several reads. In this situation, each write and read becomes a separate scan pattern with its own scan load. If loading the scan chain causes spurious writes into the RAM, Tessent FastScan destroys the data, making the reads access invalid data rather than the data that was written; therefore, the macro should be able to hold state while operating the scan chain to allow a sequence of inputs to be converted to a valid sequence of scan patterns (with a scan load per scan pattern).

For the rare case where macro outputs have paths to both leading edge and trailing edge capturing scan cells, the macrotest command includes switches that let you specify either trailing edge or leading edge observation. When you prepare the MacroTest patterns file, you can specify when to capture or observe so that the pattern matches the selection. For more information, see the -Te_observation_only and -Le_observation_only switches.

For more information on using the macrotest command, see "Using Tessent FastScan MacroTest Capability" in the *Tessent Scan and ATPG User's Manual*.

Note

When testing multiple macros, each macro opens a pattern file. When the number of open files reaches your operating system-specific limit, no more files can be opened. This may force MacroTest to fail. To avoid this problem, you may need to issue the appropriate version of limit, unlimit, or ulimit Linux shell commands before running MacroTest to increase the maximum number of files that can be open at one time. Check your Linux documentation for the appropriate command.

Arguments

- **-MULtiple_macros *macro_filename***

  A switch and string pair that test multiple macros in parallel using the macrotest commands in the *macro_filename* file. The file must contain only macrotest commands, one for each of the macros to test in parallel. Mentor Graphics recommends that you first test each macro individually in a separate run. Individual runs allow analysis if success is not possible for any single macro. When you test each macro successfully, add its corresponding command to *macro_filename* and remove it from the dofile (or command line).

Note

If you successfully tested a macro individually, you can probably test it successfully in parallel. However, Mentor Graphics cannot guarantee this due to the enormous variety of possible embeddings.

If you use the -Multiple_macros switch, you must include in the file all macros you want to be simultaneously tested. You cannot use this switch and also specify a *pattern_filename* or individual macro (by its *ID#*, *pin_pathname* or *instance_name*) on the same command line. You can test one subset of all macros using one -Multiple_macros run, with one *macro_filename* containing those macros and their pattern file specifications, and then test another subset by using another -Multiple_macros run. If you use other arguments with the -Multiple_macros switch, then macrotest uses those arguments as the default arguments for all macros in the file. For an example that uses this switch, see the Examples section at the end of this command description.

- ***ID#***

  An integer that specifies the gate identification number of the object to use in the macrotest run. The value of the *ID#* argument is the unique identification number that is automatically assigned to a gate within the design during the model flattening process.

- ***pin_pathname***

  A string that specifies the name of the input or output pin of an ATPG library model to use in the macrotest run.

- ***instance_name***

  A string that specifies the name of the instance to use in the macrotest run.

- ***pattern_filename***

  A string that specifies the name of the file containing the set of patterns to be applied to the macro.

- **-**L_H

  An optional switch that represents {L,H} as {LO,HI} output values in the macro patterns file. An error is issued if a 0 or 1 output value is specified in the macro patterns file. This is the default.

- **-**NO_L_H

  An optional switch that uses {0,1} to specify {LO,HI} output values in the patterns file, rather than the default {L,H}. If the default {L,H} is used, checking is done to ensure that the pin direction matches (output pin for L,H; input pin for 0,1). If the option -NO_L_h is issued, no such checking is possible.

- ***-VARY_observe_by_pattern***

  An optional switch that, if issued, causes MacroTest to assume that a macro may need to vary its observation path or change where it is observed at after the first successful observation path is discovered by MacroTest on the first pattern with known outputs. The default is to assume the same path can be reused without calling ATPG to verify that on each pattern.

- **-**VERBose

  An optional switch that causes all informative messages to be issued. Use this option when testing any macro for the first time, so that all information about the progress and possible issues are conveyed. This is the default.

- **-**NO_VERBose

  An optional switch that turns off the default verbose output. When using this option, important warning and informative messages may be left out.

- **-**VERIfy

  An optional switch that causes one extra simulation per pattern to verify each macro's controllability (the macro input values) and observability (the values captured into a scan cell or observed at a chip pin). The observability check verifies that complementing all macro outputs causes each scan cell or chip pin where observation is occurring to change its value if a defect caused the observed macro output to be faulty. This is the default, and you should never turn off this check to solve problems of failure to verify a pattern, which will halt the macrotest run. Instead, you must debug the issue causing the failure. Failure to verify control values typically causes simulation or tester mismatches. Failure to observe typically means that defects in the macro cannot be detected on a tester, which defeats the entire purpose of creating macrotest patterns.

- **-**NO_VERIfy

  An optional switch that refrains from performing an extra simulation per pattern to verify that the macro input values were delivered by the pattern, and that changing the macro

outputs changes the observation sites. This switch should never be used rather than investigating the cause of verification failure. Failure to control of observe the macro will either make the pattern useless, or will predict the wrong value and halt the tester.

- -MASK_nonobservation_sites

  An optional switch that places an X in all scan cells except the ones used for observation on a pattern-by-pattern basis.

  You need to specify both the -NO_FIll_patterns and the -MASK_nonobservation_sites switches to force only the scan cells used by macrotest to observe macro outputs to have known values for the scan unload. If you specify the -NO_FIll_patterns switch without also specifying the -MASK_nonobservation_sites switch, all values that propagate to scan cells are captured, regardless of whether they are from the macro outputs or from the known PIs and scan cells that fanout to both the macro inputs and other scan cells; that is, scan cells other than those observing macro outputs may have known scan-out values.

- -NO_FIll_patterns

  An optional switch that causes the unspecified bits in scan chains to remain at a value X, so that only the values needed to test the macro appear as known values. Using this option, you can see which scan chain and primary input values are needed to test the macro by using the write_patterns command. You can use the -MASK_nonobservation_sites option to convert captured values that are not needed but known to X in the scan-out.

- -TE_observation_only

  An optional switch that observes at only one of the trailing edge (TE) sites when a macro has both trailing edge and leading edge observation sites. The default is to observe at any site.

- -LE_observation_only

  An optional switch that observes at only one of the leading edge (LE) sites when a macro has both trailing edge and leading edge observation sites. The default is to observe at any site.

- -NO_REport_observation_candidates

  An optional switch that refrains from reporting the reachable observation sites. In some cases, the number of possible scan cells that an output can go to is large and the report long, so the default is not to report the candidates.

- -REport_observation_candidates

  An optional switch that reports the reachable observation sites, and whether those sites are already eliminated as observation candidates due to inability to capture. For example, a cell constraint to observe X prevents capture. If you use this switch, a list of possible observation sites (candidates) per macro output pin is displayed at the beginning of the macrotest run. The -Report_observation_candidates switch is sometimes useful for discovering that different macros in a multiple macro run have the same observation site possibilities. It also helps explain why it may be impossible to observe both macros at the same time.

The observe_at syntax in the macrotest patterns file allows you to specify where to observe one or more of the outputs of a macro for all patterns. The -Report_observation_candidates switch is useful for selecting the name(s) to use as observation site(s).

Note

Usually, it is better to let MacroTest decide where to observe, but to quickly test many macros at once, correct guidance can reduce the runtime. Incorrect guidance leads to failure to succeed where success might have been possible. Mentor Graphics recommends that you let MacroTest decide where to observe rather than restrict its choices. However, restricting observation may allow MacroTest to provide a more focused analysis of failing situations.

- -FAILure_analysis

  An optional switch that specifies the tool to determine why ATPG cannot succeed. Because this failure analysis can consume significant processing time, the default is to avoid failure analysis for rapid debug iteration. You should use this switch only as a last resort to determine why the embedding prevents justification of the macrotest pattern that causes ATPG to fail.

- [-EXHAUSTIvely_search]

  An optional switch that performs an exhaustive search. For some situations, an exhaustive search is needed; however, MacroTest can run for cpu weeks when hundreds of macros are tested together in one run. This switch only solves problems where one macro interacts with another macro; this switch is not used for problems where a single macro conflicts with its own needed boundary values and/or netlist requirements surrounding that macro. By default, this switch is omitted due to the infrequency of such debilitating macro interactions and the typical runtime cost to find them if they occur.

- -SKIP_PATterns *num_to_skip*

  An optional switch and integer pair that skips the first *num_to_skip* patterns. This option is used for analyzing problems after pattern creation when a MacroTest run fails. For example, if the third pattern fails to be converted (the transcript shows two patterns converted and simulated and then reports a failure), specify 2 for *num_to_skip*, so that MacroTest skips the first two patterns and starts on the third pattern. This enables you to quickly iterate on the problematic pattern. The -SKIP_PATterns *num_to_skip* option is not used for production patterns.

- -FIRST_OBS_pattern

  An optional switch used only for analysis when MacroTest fails. This option skips all of the control-only patterns and processes the first pattern with known (observable) macro outputs as if it were the first pattern in order to speed iterations and get to the problematic patterns sooner.

Example

The following example tests all of the macros in parallel (those with a macrotest command in the “macrofile” file). The example changes the default, whereby output 0 values in MacroTest patterns are indicated by L, and output 1 values are indicated by H. Instead, 0 and 1 are used respectively. Note that macrotest commands inside the macrofile can override the -NO_L_H switch below by selecting an alternative option. For example, one or more of the commands could use -L_H if those macros have files that use L and H to indicate 0 and 1 output values.

```
macrotest -multiple_macros macrofile -NO_L_H
```

For more examples, refer to “Using Tessent FastScan MacroTest Capability” in the *Tessent Scan and ATPG User’s Manual*.

mark_display_instances

Context: all contexts

Mode: setup, analysis

Usage

mark_display_instances {***gate_id#*** | ***instance_name*** | ***pin_pathname***}... | **-All** | **-Selected**}
[-marking_index {1 | 2 | 3 | 4 |5}] [-Display {DEBug | DESign}]

Description

Changes the color of the specified instances in the schematic windows.

You can specify up to five different colors to use in marking. The color difference can help you to quickly locate and identify particular instances in a complex schematic view. The color difference remains until you use the unmark_display_instances command to return the gate to its unmarked color.

Tip: If a gate is selected, the color applied by the mark_display_instances command is not visible until the gate is unselected.

You can change the colors used for marking by choosing **Edit > Preferences** in the DFTVisualizer and clicking the **Colors** tab. For more information, refer to "Setting DFTVisualizer Preferences" in the *Tessent Shell User's Manual*.

When you mark an object(s) by entering the mark_display_instances command into the command line (as opposed to using menus or Ctrl-M), the color assigned to Color Index 1 in the DFTVisualizer Preferences dialog box is used to mark the object(s). By default, Green is assigned to Color Index 1. For more information, refer to "Colors Preferences Dialog Box" in the *Tessent Shell User's Manual*.

Arguments

- ***gate_id#***

  A repeatable integer that specifies the gate identification number of an instance to mark. The value of the *gate_id#* argument is the unique identification number assigned to every gate in the design during the model flattening process.

- ***instance_name***

  A repeatable string that specifies the name of an instance to mark.

- ***pin_pathname***

  A repeatable string that specifies the name of a pin to mark.

- **-All**

  A switch that specifies to mark all the gates displayed.

- **-Selected**

  A switch that specifies to mark all currently selected gates.

- -marking_index {1 | 2 | 3 | 4 |5}

  An optional switch and literal pair that specifies the color to be used to mark objects in DFTVisualizer windows. By default, index 1 is used to mark objects. You can specify the color associated with each index from the Colors tab of the DFTVisualizer Preferences dialog box when Marked is selected. For more information on marking, see "Customizing Marking Colors in the Schematic Windows" and "Marking and Unmarking Objects in the Windows".

- -Display {DEBug | DESign}

  A switch and literal pair that specifies the window for which to apply the mark_display_instances command. The following literals can be used with the -Display switch:

  DEBug
  Applies the settings to the Debug window. This is the default behavior.

  DESign
  Applies the settings to the Design window.

Examples

The following example marks two instances using the color set as Color Index 3, specifying the instance name of one and the gate identification number (85) of the other:

```
mark_display_instances /i$142/q 85 -marking_index 3
```

unmark_display_instances

migrate_layout

Context: patterns -scan_diagnosis

Mode: analysis

Usage

migrate_layout ***ldb_directory*** **-ladb** ***preexisting_ldb*** [-vdb *preexisting_vdb*]

Description

Generates an LDB directory hierarchy that contains the specified preexisting LDB.

Use this command to copy a preexisting LDB into the LDB directory hierarchy that became available with the Tessent Diagnosis 2013.2 release. This command allows you to upgrade to the LDB directory without regenerating the LDB from the LEF/DEF files. The tool automatically copies the preexisting LDB into the new LDB directory.

For the DFM diagnosis flow, use this command to additionally copy a preexisting violations database (VDB), which was generated automatically during DFM diagnosis, into the new LDB directory.

Arguments

- ***ldb_directory***

  A required string that specifies the pathname to a new LDB directory.

- **-ladb** ***preexisting_ldb***

  A required switch and string pair that specifies the pathname to a preexisting LDB.

- **-vdb** ***preexisting_vdb***

  An optional switch and string pair that specifies the pathname to a preexisting VDB.

Example

The following example generates a LDB directory named mylayoutdb. It then copies the example2.ldb and example_dfm.vdb databases into the LDB directory.

```
migrate_layout newlayoutdb -ladb preexisting.ldb -vdb preexisting_dfm.vdb
```

move_config_element

Context: dft

Mode: analysis

Usage

move_config_element ***object_spec***
[-in_wrapper *wrapper_name_or_object*]
[-before *before*| -after *after* | -first | -last]
[-replace]

Description

Moves a configuration element from one location to another.

Repeatable and non-repeatable wrappers and repeatable properties can be moved from one wrapper to another. Single wrappers and properties can only be moved within their parent wrapper.

Arguments

- ***object_spec***

  A value that specifies the name of a configuration element or a collection containing one configuration element to be moved. When using the -in_wrapper option, the name is the relative pathname with respect to the specified wrapper. When not using the -in_wrapper option, the name is the complete pathname with respect to the root of the partition. To move an element from one wrapper to the next, you must use the get_config_elements or the "get_config_value -object" command to get the object and use it as the object_spec. The moved element must not already exist in the destination wrapper unless the -replace option is used, in which case the existing element will be deleted before being replaced by the moved one.

  When the allowed content of the destination parent wrapper is defined with Wrapper, the metadata definition of the source and destination element must be identical (both definition must reference the same metadata definition). If this is not the case, an error message is generated.

- -in_wrapper *wrapper_name_or_object*

  An option value pair that specifies that the configuration element is to be moved inside a specific wrapper. The *wrapper_object_spec* can be the complete name of a wrapper relative to the root of the partition or a collection containing a single wrapper element as returned by get_config_elements or "get_config_value -object". When the -in_wrapper is not specified, the destination parent wrapper is assumed to be the same as the source parent wrapper unless the -before or -after option is specified.

- -before *before*

  An optional option value pair that specifies the configuration element in front of which to move the new configuration element. When the -before option is used with a collection

containing a configuration element object, the -in_wrapper option cannot be used because the parent wrapper is extracted from the object.

When config_object_spec is a name, it must be a name relative to the wrapper specified with the -in_wrapper option. If the -in_wrapper option is not specified, it is a name relative to the root of the partition.

The -before option is mutually exclusive with the -after, -first, and -last options. When none of those four option is specified, -last is assumed.

- -after *after*

  An optional option value pair that specifies a configuration element after which to move the new configuration element. When the -after option is used with a collection containing a configuration element object, the -in_wrapper option cannot be used because the parent wrapper is extracted from the object.

  When config_object_spec is a name, it must be a name relative to the wrapper specified with the -in_wrapper option. If the -in_wrapper option is not specified, it is a name relative to the root of the partition.

  The -after option is mutually exclusive to the -before, -first and -last options. When none of those four option is specified, -last is assumed.

- -first

  An optional option that specifies to move the new configuration element before any other element in the parent wrapper.

  The -first option is mutually exclusive to the -before, -after and -last options. When none of these four options is specified, -last is assumed.

- -last

  An optional option that specifies to move the new configuration element after all other elements in the parent wrapper.

  The -last option is mutually exclusive to the -before, -after, and -first options. When none of those four option is specified, -last is assumed.

- -replace

  An optional option that suppresses the error that is normally generated when moving a configuration element from one wrapper to another and the leaf_name conflicts with an existing element in the destination wrapper. The error only occurs if the name is defined as not repeatable in the metadata. Instead of an error, the existing element is first deleted.

Example

The following example moves configuration elements within and across parent wrappers.

```
> set_transcript_style input_only
> set dft [add_config_element DftSpecification(moda,rtl)]
{/DftSpecification(moda,rtl)}
> set ijtag [add_config_element IjtagNetwork -in_wrapper $dft]
{/DftSpecification(moda,rtl)/IjtagNetwork}
> set host [add_config_element HostScanInterface(1) -in_wrapper $ijtag]
{/DftSpecification(moda,rtl)/IjtagNetwork/HostScanInterface(1)}
> set sib1 [add_config_element sib(1) -in_wrapper $host]
{/DftSpecification(moda,rtl)/IjtagNetwork/HostScanInterface(1)/Sib(1)}
> set sib2 [add_config_element sib(2) -in_wrapper $host]
{/DftSpecification(moda,rtl)/IjtagNetwork/HostScanInterface(1)/Sib(2)}
> set sib3 [add_config_element sib(3) -in_wrapper $host]
{/DftSpecification(moda,rtl)/IjtagNetwork/HostScanInterface(1)/Sib(3)}

move_connections

Context: all contexts

Mode: insertion

Usage

move_connections **-from *obj_spec1* -to *obj_spec2*** [-net_name *net_name*] [-silent]

Description

Moves connections from pin or net objects to pin objects.

The -from obj_spec1 argument is assumed to be a net when the -to obj_spec2 argument is one level below the hierarchy of obj_spec1. For example, the following command moves the u1/a pin to the *net* by the name of u1/a, instead of the pin, because u1/u2/b is below u1.

```
move_con -from u1/a -to u1/u2/b
```

In another example, u2/b is not below u1. In this case, the command creates the connection to the u1/a *pin* instead of to the net.

```
move_con -from u1/a -to u2/b
```

The specific behavior of the move_connections command varies based on the object type found inside obj_spec1.

If the object within obj_spec1 is:

- a pin

  The net connected to this pin is moved to the pin specified in obj_spec2 and the pin in obj_spec1 is left unconnected.

- a net that is also an input port

  The net is renamed everywhere it is used and is then connected to the pin in obj_spec2. The input port is left with no fanout. The renamed net name is the specified -net_name value or the original net name, when the -net_name option is not specified, uniquified using the _ts# suffix.

- a net that is also an output port

  The net is renamed everywhere it is used and is then connected to the pin in obj_spec2. The output port is left with no fanin. The renamed net name is the specified -net_name value or the original net name, when the -net_name option is not specified, uniquified using the _ts# suffix.

- a net that is not also a port

  The net is renamed everywhere it is used, except at its driver source, and is then connected to the pin in obj_spec2. The driver source is left connected to the original net with no fanout. The renamed net name is the specified -net_name value or the original net name, when the -net_name option is not specified, uniquified using the _ts# suffix.

The obj_spec1 must be a single pin or net name, a Tcl list of pin or net names, or a collection of pin or net objects. The obj_spec2 must be a single pin name, a Tcl list of pin names or a collection of pin objects. The obj_spec1 and obj_spec2 must have exactly the same size. The -from and -to objects must exist in the same instance; a move is not allowed across hierarchy.

This command returns a collection containing the net object that ends up being connected to the pin object in obj_spec2. If the -from object is a pin, the command returns the nets that were moved. If the -from object is a net, the command returns the nets that were created.

If an object does not exist in obj_spec1 or obj_spec2 and the -silent option is specified, the object is ignored and the move action skipped. If an object does not exist and the -silent option is not specified, the tool generates an error.

You must be careful when using the move_connections command inside a non-uniquified design. You must only do the move or disconnection once per module and once per generate loop count. See how the parent_instance and the leaf_name_hash attributes are used in section 3 of Example 5 in the get_dft_cell command description to perform this robustly.

Arguments

- **-from *obj_spec1***

  A required switch and value pair that specify the object to be moved. The obj_spec1 must be a single pin or net name, a Tcl list of pin or net names, or a collection of pin or net objects.

- **-to *pinObj2***

  A required switch and value pair that specifies the pin to which the net is moved to. The obj_spec2 must be a single pin name, a Tcl list of pin names, or a collection of pin objects. The obj_spec1 and obj_spec2 must have exactly the same size. The -from and -to objects must exist in the same instance; a move is not allowed across hierarchy.

- -net_name *name*

  An optional argument that specifies the base net name to create when moving a net. The new net name is the specified -net_name value or the original net name when the -net_name option is not specified, uniquified using the _ts# suffix.

- -silent

  An optional argument that specifies to ignore specified objects that do not exist and to ignore the move connection without generating an error message. The returned net object is null.

Example 1

This following example moves the net connected to input pin u1/a to the input pin u2/b. After the operation, pin u1/a is left with no driver.

```
move_connections -from u1/a -to u2/b
```

Example 2

The following example shows how to intercept an input pin from the inside of the instance. By using the get_net introspection command, the net named u1/u2/a is returned instead of the pin as in the previous example. The parent_instance of the net automatically returns u1/u2 which results in the intercepting gate being placed inside the module as required.

```
set net [get_net u1/u2/a]
set gate_inst_name [lindex [get_attribute_value_list $net -name parent_instance] 0]/mygate
set gate_inst [create_instance $gate_inst_name -of_mod and2 -allow_inst_uniquification]
move_connections -from $net -to [get_pins y -of_instance $gate_inst]
create_connections $net [get_pins a -of_instance $gate_inst]
```

Figure 7-17. Intercepting an Input Pin From Inside An Instance

Example 3

This following example shows how to intercept an output port from the inside of the current design. The parent_instance of the port automatically returns a null value which results in the intercepting gate being placed inside the root module as required. The net names created by the move_connections and create_connections commands are derived from the net named being moved or connected. You can use the -net_name option if you want a specific net name to be used instead.

```
set port y
set gate_inst_name [lindex [get_attribute_value_list $port -name parent_instance] 0]/mygate
set gate_inst [create_instance $gate_inst_name -of_mod mygate -allow_inst_uniquification]
move_connections -from $port -to [get_pins a -of_instance $gate_inst]
create_connections $port [get_pins y -of_instance $gate_inst]
```

Figure 7-18. Intercepting an Output Port From Inside the Current Design

Example 4

This following example shows how to intercept an input pin from the outside of the instance. This example also shows the use of the parent_instance attribute to properly determine the location of the intercepting gate that must be placed in the same hierarchy level as the intercepted net. Notice that the return value of the create_instance command is used to update the gate_inst value in case the original name already existed inside the design, and the create_instance command created a new uniquified name. The net that was connected to the pin u1/u2/a ends up connected to pin “a” of $gate_inst. Following the move_connections operation, pin u1/u2/a is left open. The create_connections command is then used to reconnect it to the output of the intercepting gate.

```
set pin u1/u2/a
set gate_inst_name [lindex [get_attribute_value_list $pin -name parent_instance] 0]/mygate
set gate_inst [create_instance $gate_inst_name -of_mod and2 -allow_inst_uniquification]
move_connections -from $pin -to [get_pins a -of_instance $gate_inst]
create_connections $pin [get_pins y -of_instance $gate_inst]
```

Figure 7-19. Intercepting an Input Pin From Outside An Instance

Example 5

The following example shows how to intercept an output pin from the outside of the instance. This example also shows the use of the parent_instance attribute to properly determine the location of the intercepting gate that must be placed in the same hierarchy level as the intercepted net. Notice that the return value of the create_instance command is used to update the gate_inst value in case the original name already existed inside the design, and the create_instance command created a new uniquified name. The net that was connected to pin u1/u2/y ends up connected to pin y of $gate_inst. Following the move_connections, pin u1/u2/y is left open. The create_connections command is then used to reconnect it to the input of the intercepting gate.

```
set pin u1/u2/y
set gate_inst_name [lindex [get_attribute_value_list $pin -name parent_instance] 0]/mygate
set gate_inst [create_instance $gate_inst_name -of_mod and2 -allow_inst_uniquification]
move_connections -from $pin -to [get_pins y -of_instance $gate_inst]
create_connections $pin [get_pins a -of_instance $gate_inst]
```

no_transcript

Context: unspecified, all contexts

Mode: all modes

Usage

no_transcript { ***command1 command2 ...*** }

Description

Turns off transcripting for the specified commands.

This command is useful when you are writing Tcl procedures in which you do not want your embedded commands to show up in the transcript or log file. The no_transcript command is also not transcripted.

Arguments

- ***command1 command2 ...***

  A required string that specifies the commands that you do not want to appear in the transcript or log file.

Example

The following excerpt from a Tcl procedure (see get_dft_cell, example 5, for the full Tcl procedure), shows a usage example for the no_transcript command:

```
#####################################################################
### Section 5: Retrieves leaf instance name of gate if node is a
### repeated module instance and skips the interception
#####################################################################

if {[info exists insertion_parent_leaf_instance_array($key)] && \
      [get_insertion_option -auto_uniquify_edited_modules] eq "off"} {
   set leaf_cell_inst "$insertion_parent_leaf_instance_array($key)"
   if {$leaf_block_id ne ""} {
      set cell_inst [get_instance \
         "${parent_instance_name}/${leaf_block_id}.${leaf_cell_inst}"]
   } else {
      set cell_inst [get_instance \
         "${parent_instance_name}/${leaf_cell_inst}"]
   }
} else {
   if {$leaf_block_id ne ""} {
      set cell_inst_name \
      "${parent_instance_name}/${leaf_block_id}.insertion_${cell_sel}"
   } else {
      set cell_inst_name \
         "${parent_instance_name}/insertion_${cell_sel}"
   }
   no_transcript {
      set cell_inst [create_instance $cell_inst_name -of_module \
         $dft_cell -allow_instance_uniquification]
   }

   set leaf_name [lindex [get_attribute_value_list $cell_inst -name \
      leaf_name] 0]
   set leaf_block_id [lindex [get_attribute_value_list $cell_inst \
      -name leaf_block_id] 0]
   if {$leaf_block_id ne ""} {
      # Remove the block_id part from the leaf instance name
      set leaf_name [string range $leaf_name \
         [string length $leaf_block_id] end]
   }
   set insertion_parent_leaf_instance_array($key) $leaf_name

   if {$insertion_type == "sink"} {
      no_transcript {
         move_connections -from $node_object \
            -to [get_pins ${input0} -of_instances  $cell_inst]
         create_connections [get_pins ${output} -of_instances \
            $cell_inst] $node_object
      }
   } else {
      no_transcript {
         move_connections -from $node_object -to [get_pins ${output} \
            -of_instances $cell_inst]
         create_connections $node_object [get_pins ${input0} \
            -of_instances  $cell_inst]
      }
```

```
         }
      }

      if {$connect_in2} {
         no_transcript {
            create_connections $in2_object [get_pins $input1 -of_instances \
               $cell_inst]
         }
      }

      if {$connect_sel} {
         no_transcript {
            create_connections $sel_object [get_pins $select -of_instances \
               $cell_inst]
         }
      }
      return $cell_inst
   }
```

open_layout

Context: patterns -scan_diagnosis

Mode: analysis

Usage

Layout-Aware Diagnosis Flow

open_layout ***layout_database_name*** [-VERIfy [-EXTRA_LAYout_hierarchy ***extra_levels_of_hierarchy_in_layout***> | -EXTRA_DESign_hierarchy ***extra_levels_of_hierarchy_in_design***>]] [-THreshold ***percentage_match***]

SVDB Layout Marker Flow

open_layout **-SVDB** ***svdb_directory_name*** [-32]

Description

Layout-Aware Diagnosis Flow

Opens an existing Tessent Diagnosis tool-compatible Layout Database directory.

Any subsequent usage of this command first closes any existing layout before Tessent Diagnosis opens a new Layout Database. See "Layout-Aware Diagnosis" in the *Tessent Diagnosis User's Manual* for complete information on this flow.

Layout-Aware Diagnosis Flow with DFM

Opens an existing Tessent Diagnosis tool-compatible Layout Database and if this database contains imported DFM information, the layout-aware diagnosis results will be annotated with DFM hit results.

For more information, see "Diagnosis for Design for Manufacturability Analysis."

SVDB Layout Marker Flow

Checks out a *calibreqdb* license and invokes the 64-bit Calibre Query Server software in the background on workstations supporting 64-bit. Otherwise, Tessent Diagnosis executes this command in 32-bit mode. Before using this command, you must have a valid SVDB directory containing net name information and set the CALIBRE_HOME environment variable to your Calibre software tree.

Arguments

- ***layout_database_name***

  A required string that specifies the name of the existing Layout Database directory created with the create_layout command.

Layout-Aware Diagnosis Flow

- -VERIfy

  An optional switch that specifies to perform verification if the current design has not been validated against the current Layout Database. Using this option ensures that in subsequent runs the layout database can be opened for the current design without having to re-run verification.

  At the time of opening the layout, Tessent Diagnosis checks whether the current design has been verified against the current Layout Database. If the current design has not been validated, it performs verification. During verification, layout rule violation information is added to the layout database.

  For each flat model used during diagnosis, you must first perform the verification step. You can do this with the open_layout -verify command. With subsequent diagnosis runs using a verified flat model/LDB combination, you can skip the verification step by just specifying open_layout. If you need to verify many flat models against the same LDB, you can use open_layout -verify to verify them in parallel in separate diagnosis sessions.

  Layout verification rules can be divided into two broad categories: those that check the consistency of LEF/DEF files themselves, and those that match design information with the layout. Only the second type of layout verification rules are re-evaluated when a layout database is verified against a new design. Because the LEF/DEF layout information has not changed, the first type of rules do not need to be re-run.

- -EXTRA_LAYout_hierarchy ***extra_levels_of_hierarchy_in_layout***

  An optional switch and string pair that removes extra levels of layout hierarchy such that the design hierarchy and layout hierarchy match. You can only specify this switch once, otherwise the tool issues an error and exits.

  You use this switch if your design is a subset of a larger layout hierarchy. You can specify multiple levels of hierarchy in one string with no spaces.

  This switch can only be used in conjunction with the -verify switch.

- -EXTRA_DESign_hierarchy ***extra_levels_of_hierarchy_in_design***

  An optional switch and string pair removes extra levels of design hierarchy such that the layout hierarchy and design hierarchy match. You can only specify this switch once, otherwise the tool issues an error and exits.

  You use this switch if your layout is a subset of a larger design hierarchy. You can specify multiple levels of hierarchy in one string with no spaces.

  This switch can only be used in conjunction with the -verify switch.

- -THreshold ***percentage_match***

  An optional switch and integer pair specifies the minimum percentage match threshold required to successfully complete a layout verification of the LEF/DEF files, and subsequent verification of the layout database. The default threshold value is 85 percent.

SVDB Layout Marker Flow

- **-SVDB *svdb_directory_name***

  A required switch and string pair that specifies the name of a valid SVDB directory. The SVDB must contain net name information.

- -32

  An optional switch invoking the 32-bit version of the Calibre Query Server software. The 64-bit version is the default.

Example 1

In the following example, Tessent Diagnosis loads the existing Layout Database (*design.layout*) into memory:

```
open_layout design.layout
```

Example 2

The following example illustrates using the -VERIfy switch with the open_layout command for two designs: *DesignA.flat* and *DesignB.flat*. Except for different pin constraints, the two designs are essentially identical. Because a high percentage of the logic overlaps, both designs use the same Layout Database for layout-aware diagnosis.

To perform layout-aware diagnosis on these two designs using the same Layout Database, you do the following:

1. Create and verify the Layout Database, in this example *DesignA_layout_database*, with *DesignA.flat* using the create_layout command.
2. Invoke Tessent Diagnosis in scan diagnosis mode and read in the *DesignB.flat* flat model with the read_flat_model command.
3. Using the open_layout command and -VERIFy switch, open the *DesignA_layout_database* with the DesignB.flat model as in the following:

   ```
   open_layout -verify DesignA_layout_database
   ```

   This verifies *DesignB.flat* against the newly-created *DesignA_layout_database*.
4. Proceed with layout-aware diagnosis with *DesignB.flat*.

open_pattern_set

Context: patterns -ijtag

Mode: analysis

Usage

open_pattern_set **pattern_set_name [**-timeplate *timeplate* **|** -tester_period *tester_period***]** **[**-tck_ratio *tck_ratio***] [**-no_initial_ireset**] [**-replace**]**

Description

Opens an empty named pattern set and makes it ready to be populated with the specified PDL commands.

A populated pattern set is closed using the close_pattern_set command. An existing pattern set cannot be overwritten unless it is first deleted or the -replace option is used.

PDL commands can only be specified when a pattern set is open with the exception of the iReset and iCall commands which can also be specified within the test_setup and test_end procedures in the patterns -scan context.

You use the -timeplate switch to specify the timeplate for this pattern set. Specifying a different timeplate is rarely needed as the default timeplate is adequate for standard ijtag operations. Tessent Shell automatically defines the appropriate timeplate based on the specified off value for TCK and the specified -tck_ratio option value. The only time you need a different timeplate is in the rare situation you want to define clock waveforms with more than two edges.

The -tck_ratio option defaults to 1. You must specify a larger value if you have synchronous clocks (add_clocks commands without the -period option). In this case, you specify -tester_period to match your system clock requirements and specify a -tck_ratio value such that TCK toggles at a rate that is not higher than it was designed for.

If all your system clocks are asynchronous (add_clocks commands with the -period option), allow -tck_ratio to default to 1 and specify -tester_period to match your TCK period requirements. Figure 7-21 through Figure 7-28 illustrate the TCK timing and the position of the ScanOut strobing relative to the rising edge of TCK. Notice how, independent of the off value for TCK and the specified tck_ratio value, ScanOut is always strobed one percent of the TCK period before the rising edge of TCK.

With a custom timeplate, you can specify different timing for the measurements and forces of ScanIn, ScanOut and TCK; however, the measurement time for ScanOut must be before the rising of TCK and after the falling edge of TCK when the off value for TCK is 1. For more information about timeplates, refer to "Timeplate Definition" in the *Tessent Shell User's Manual*.

   pulse_clock t_time t_width;
   period tester_period;
end;
```

Arguments

- **pattern_set_name**

  A required string that defines the name of the pattern set. This name uniquely identifies the pattern set for later use with write_patterns. This name also specifies the name of the iProc, if the pattern set is written out in -pdl format.

Note

The pattern set names “test_setup” and “test_end” are not allowed.

- -timeplate *timeplate*

  An optional switch and string pair that specifies the name of a valid timeplate, defined in a procedure file reference with the set_procfile command. This option is mutually exclusive with the -tester_period option as the tester_period is specified within the timeplate when the -timeplate option is used.

- -tester_period *tester_period*

  An optional switch and value pair that specifies the tester period when the built-in timeplate, shown in Figure 7-21 through Figure 7-28, is used. The default value is 100.0 ns. The default unit when omitted is nanosecond.

  Note that you can use this switch to specify that the Verilog testbench has a precision smaller than its resolution. For more information, refer to the description of the “set time scale” statement in the *Tessent Shell User’s Manual*.

- -no_initial_ireset

  An optional switch that specifies to create a pattern set that is to run after another one while keeping power and clocks active between them. You may need to create a pattern set of this type if you need to insert some ATE actions in the middle of a test such as changing a voltage. These types of pattern sets are exported together when writing out the Verilog test bench and as separate STIL or WGL files when exporting the pattern files to use on the ATE. You should use special care when running these patterns on the ATE because the lack of a reset at the beginning of the pattern makes it impossible to quit in the middle of the pattern and resume from the start when the capture memory is filled up. Data logging on such patterns can only be done in one pass and to the extent of the size of the capture memory on the ATE equipment.

  The -no_initial_ireset option cannot be used on the first open_pattern_set command of a session. When used on a subsequent open_pattern_set command, the end ICL state of the previous pattern_set is used as the beginning ICL state for the current pattern set.

- -tck_ratio *tck_ratio*

  An optional switch and value pair that specifies the ratio between the required TCK period and the tester_period used for this pattern set. The tester period is the value specified with the -tester_period option when using the built-in timeplate or the period entry of the timeplate referenced by the -timeplate option. The default value is 1.

- -replace

  An optional switch that specifies to replace an existing pattern set with the same name.

Return value

None

Example

The following example opens a pattern set called pat1 using the built-in timeplate described in Figure 7-21. The tester_period is over-written to 50 ns. The same pattern set is later replaced by one where the timeplate TP1 is used. TP1 is a timeplate defined inside a procfile and referenced by the set_procfile command in setup mode.

```
open_pattern_set pat1 -tester_period 50ns
iCall myProc
close_pattern_set

open_pattern_set pat1 -timeplate TP1 -replace
```

reset_open_pattern_set

open_tsdb

Context: all contexts

Mode: all modes

Usage

open_tsdb *directory_path_list* [-silent]

Description

Makes the content of TSDB directory visible to the tool. The specified TSDB output directory is automatically opened and does not need to be opened with this command.

Many actions are taken on the opened TSDBs at various steps in the design flow. Some of those actions are described here:

- When the set_current_design command is invoked, the tool automatically reads in the most recent <module_name>.<format>_interface file using the read_verilog or read_vhdl -blackbox option if the corresponding <module_name> does not already exist in memory. This enables you to only load the modules associated to the current design and have the interface view of all child physical or sub blocks loaded automatically.
- All dft_inserted_designs and instruments sub-directories are automatically searched and ICL files corresponding to design modules are automatically loaded after design elaboration.
- The is_physical_module attribute is automatically set on all modules found in a TSDB that were declared as physical blocks using the set_design_level command when they were processed by the tool.

Arguments

- *directory_path_list*

  A required value containing an absolute or relative path to a TSDB directory, or a Tcl list containing one or many absolute or relative paths to TSDB directories. The tool verifies that each specified directory path is an existing TSDB directory and that only one copy of instrument and dft_inserted_design directories exists for any given module/design_id combination in all opened TSDBs; if this is not the case and you get this error, you must close the redundant TSDB directories using the close_tsdb command.

- -silent

  An optional switch that suppress the warning that is normally generated if the specified directory_path is already opened.

Examples

The following example opens three TSDB directories with one command invocation.

```
> open_tsdb [list ${tsdb_home}/corea.tsdb \
                  ${tsdb_home}/coreb.tsdb \
                  ${tsdb_home}/corec.tsdb ]
> get_tsdb_list
/home/projects/chipa/tsdbs/corea.tsdb /home/projects/chipa/tsdbs/coreb.t
sdb /home/projects/chipa/tsdbs/corec.tsdb
```

get_tsdb_output_directory

open_visualizer

Context: unspecified, all contexts

Mode: all modes

Usage

open_visualizer [-Display ***window*** **|** ***-Restart***]

Description

Opens the main DFTVisualizer window.

You can also use the following commands to open DFTVisualizer and display the Debug window:

- analyze_drc_violation
- add_display_instances
- analyze_fault (Tessent FastScan and Tessent TestKompress only)

Displayed data remains persistent throughout a tool session.

Arguments

- -Display ***window***

  An optional switch and literal pair that specifies which windows display when DFTVisualizer opens. Valid literals include:

  DEBug — opens the Debug window.

  DESign — opens the Design window.

  Browser — opens the Browser window which contains the Hierarchy, Library, and Clocks tabs.

  SIgnals — opens the Signals window.

  DAta — opens the Data window.

  Wave — opens the Wave window.

  SEarch — opens the Global Search window.

  Format — opens the Format Guide window.

  TRanscript — opens the Transcript window.

  TAskmgr — opens the Task Manager window.

  TExt_editor — opens the Text Editor window.

  TESt_structures — opens the Test Structures window.

- -Restart

  An optional -Restart switch that enables you to restart DFTVisualizer following an application error in DFTVisualizer without restarting the entire tool. This eliminates the need to exit and re-invoke the parent application.

  This option closes the current DFTVisualizer window and opens a new DFTVisualizer session displaying either the default windows normally opened at invocation or those windows specified to be open in your saved preferences. This option does not restore any of the tool data contained in DFTVisualizer windows prior to the error.

Tip: If you execute the same set of commands that resulted in the application locking up, the same error will occur and the application will lock up again. You can use the -Restart option and then avoid the same error a second time by following a different set of steps or by skipping the step that resulted in the error.

Examples

The following example opens DFTVisualizer and displays the Debug, Design, and Transcript windows.

```
open_visualizer -display debug design transcript
```

order_patterns

Context: dft -edt, patterns -scan

Mode: analysis

Usage

order_patterns [*number_of_passes* | Auto ***percentage***]
[-Init_order Normal | REverse | RAndom] [-Simulate]
[{-CAPture_power [ST_Peak | ST_Average | WSA_Peak | WSA_Average]
| -SHIft_power **LOAD | RESPonse**}[-INSTance ***instance_name***
| -MODUle ***module_name***] [-ASCending | -DEScending]]

Description

Reorders the internal test pattern set as specified.

Test patterns can be rearranged to detect the most faults first, which is useful for:

- Truncating the test pattern set in order to fit it in the ATE memory
- Detecting failing chips as early as possible during testing.

Multiple load patterns are ranked according to the average number of faults detected per scan load, ensuring that on average the patterns that detect the most faults per scan load are first. This command supports stuck-at and transition fault models, as well as timing-aware ATPG. This command does not support MacroTest or parametric patterns.

The order_patterns command does not remove ineffective patterns. If you want to remove ineffective patterns, use the compress_patterns command.

This is a multiprocessing command. For more information about multiprocessing, refer to "Using Multiprocessing to Reduce Runtime" in the *Tessent Scan and ATPG User's Manual*.

Note

Using the order_patterns command turns off pattern classification until you issue a "set_pattern_classification On" command.

Arguments

- *number_of_passes*

  An optional integer that specifies the number of passes to make through the data when reordering the pattern set. By default, one pass is made.

- -Auto *percentage*

  An optional switch and integer pair that reorders the pattern set iteratively until further reordering produces negligible improvement in the number of patterns needed to achieve a given fault coverage benchmark. The tool determines the given fault coverage benchmark by subtracting *percentage* from the total fault coverage (FC) achieved using all the patterns

in the internal pattern set. The *percentage* argument must be a non-negative number less than or equal to FC.

Reordering stops when either of the following conditions exist:

- The tool completes a maximum of 100 iterations.
- The number of patterns that is needed to achieve the given fault coverage benchmark decreases by less than 1% from one iteration to the next. This stop point can be stated mathematically as:

$(P_{FCb})_{previous_pass} - (P_{FCb})_{current_pass} < (P_{FCb})_{previous_pass} \times .01$

where: P_{FCb} = number of patterns needed to achieve the fault coverage benchmark
FCb = FC - *percentage* = fault coverage benchmark
FC = total fault coverage achieved using all the patterns in the pattern set

- -Init_order Normal | REverse | Random

  An optional switch and literal pair that specifies the initial pattern ordering to use as a starting point for pattern reordering. The literal choices are as follows:

  Normal — A literal that specifies the order of the current internal pattern set as the initial pattern order.

  REverse — A literal that specifies to use the reverse order of the current internal pattern set as the initial pattern order.

  Random — A literal that specifies to randomize the order of the current internal pattern set, and use the random order as the initial pattern order.

- -Simulate

  An optional switch that fault simulates the test patterns after reordering.

- -CAPture_power [ST_Peak | ST_Average | WSA_Peak | WSA_Average]

  Optional switch and literal pair that orders test patterns based on switching activity during capture. Literal options include:

  ST_Peak — Peak of state transitions. Default.

  ST_Average — Average of state transitions.

  WSA_Peak — Peak of weighted switching activity.

  WSA_Average — Average of weighted switching activity.

- -INSTance ***instance_pathname***

  An optional switch and string that orders test patterns based on switching activity associated with a specified instance. The instance_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- -MODule ***module_name***

  An optional switch and string that orders test patterns based on switching activity associated with a specified module. The module_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- -SHIft_power {**LOAD** | **RESPonse**}

  Optional switch and literal that orders test patterns based on switching activity during shift. Literal options include:

  LOAD — based test pattern loading.

  RESPonse — based on circuit response.

- -ASCending | -DEScending

  Optional switch that orders test patterns with respect to the amount of switching activity. By default test patterns are ordered in an ascending order.

Example 1

Total fault coverage is 98%, and there are 2,500 patterns in memory. The following example reorders patterns in the internal pattern set until the difference between the number of patterns that is needed to achieve 93% (98 - 5) fault coverage in the current pass and the previous pass is less than 1% of the number of patterns in the previous pass:

order_patterns auto 5

Example 2

The following example creates test patterns, and then reorders them based on the average weighted switching activity in capture cycles:

create_patterns
order_patterns -capture_power wsa_avg ascending

```
//  Warning: Pattern classification is turned off.
```

Related Commands

add_processors
report_patterns
compress_patterns
set_pattern_buffer
set_pattern_classification
set_pattern_filtering

printenv

Context: unspecified, all contexts

Mode: all modes

Usage

printenv

Description

Prints out the values of the Linux variables in the environment.

The printenv command allows the Linux printenv command to be available as a common DFT command, for convenience in displaying Linux environment variables. Linux environment variables are automatically available as variable references within the tool.

Examples

The following example prints out the values of the Linux variables in the environment:

```
printenv
```

process_dft_specification

Context: dft

Mode: setup, analysis

Usage

process_dft_specification [*id*] [-no_insertion [-design_name *design_name*]] [-validate_only] [-transcript_insertion_commands]

Description

Validates and processes the content contained in a DftSpecification wrapper.

If you specify the -validate_only option, this command only validates the Dft specification. If you specify the -no_insertion option, the command validates and generates the Dft components. When used without either of these two options, the command validates the specification, generates the Dft components such as the RTL and the ICL description, and inserts them into the design. The insertion can be done at the netlist or the RTL level depending on the set_context -no_rtl versus -rtl option that was specified when setting the context.

If the DftSpecification being processed has a HostScanInterface/Interface consisting of only ports on the current design and the -no_insertion option is not specified, the add_icl_scan_interfaces and the set_icl_scan_interface_ports commands are issued during the insertion stage such that if you perform ICL extraction after the insertion, the ScanInterface will be named using the *id* of the HostScanInterface contained in the DftSpecification.

The data created by this command is stored inside the directory returned by the get_tsdb_output_directory command which defaults to *./tsdb_outdir* unless it has been changed by the set_tsdb_output_directory command.

process_dft_specification.post_insertion Procedure

When performing the insertion (i.e. when neither the -validate_only nor -no_insertion switch is specified), the modified design is written out inside the "*tsdb_output_directory/dft_inserted_designs*" directory. If you need to perform custom editing between the insertion of the Dft components and the saving of the design, you can define a Tcl proc with the name "process_dft_specification.post_insertion" and it will automatically be called after all Dft components have been inserted and before the write_design command is invoked.

To develop this type of procedure, execute all of your custom editing commands interactively in Tessent Shell in the insertion mode. When you are finished, create the Tcl proc with those commands in it; the Tcl proc will then be called when rerunning process_dft_specification. If you need to instantiate new modules inside the design as part of this Tcl proc, you must read them in using read_verilog or read_vhdl in setup mode prior to invoking process_dft_specification.

The process_dft_specification.post_insertion procedure must have two arguments as shown in the following example. The first argument holds the configuration element object that is currently being processed. The second argument holds a list of option value pairs corresponding to the options that were used when the process_dft_specification command was called.

```
proc process_dft_specification.post_insertion { root_wrapper args } {

  # "$root_wrapper" is the config_element object being processed.
  # "get_config_value $root_wrapper -id 0" returns the design_name
  # "get_config_value $root_wrapper -id 1" returns the id

  # "$args" is a list of option value pairs that reflects the options used
  # when the process_dft_specification command was called.

  array set extra_args $args

  # $extra_args(-instrument_prefix) returns the value of that option

}
```

Licensing

This command normally requires an IJTAG product license to run. There is one exception to this requirement. If the design contains one or more instances of an EDT/LBIST controller, the TestKompress/LogicBist licenses are also allowed to run this command. In this case, the tool checks the availability of the license in the following order: IJTAG, TestKompress, LogicBist. If none are currently available, the tool queues up for the first license that you own.

You can refer to the set_license_queue_timeout and get_license_queue_timeout commands for more information about the license queuing feature.

Arguments

- *id*

  An optional string that specifies the DftSpecification wrapper that is to be processed. As described in the DftSpecification wrapper syntax, the wrapper is identified by the two strings *design_name* and *id*. If you only have one DftSpecification wrapper present in memory that matches DftSpecification(*design_name*,*), you can omit the id from the process_dft_specification command. However, if several DftSpecification wrappers matching DftSpecification(*design_name*,*) exist in memory, you must specify the appropriate id when executing the process_dft_specification command. Refer to the following -design_name option to understand how the *design_name* value is obtained.

- -no_insertion

  An optional switch that specifies to not perform the insertion of the Dft components into the design. When this option is specified, no design is needed because no insertion is performed. Some validations, such as verifying that the specified parent_instance properties in the Sib, ScanMux and Tdr wrappers actually exist in the design, are only performed when this switch is omitted. If you execute the process_dft_specification command without this option and the set_current_design command has not yet been issued, an error is generated.

- -design_name *design_name*

  An optional switch and string pair that specifies the *design_name* value used to identify the DftSpecification wrapper when the -no_insertion option is specified. The -design_name value defaults to the current design if it has been set with the set_current_design command.

If the current design has not been set, it is extracted from the DftSpecification wrapper existing in memory.

When the id is specified, if exactly one wrapper matches “DftSpecification (*,<id>)” in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified. When the id is not specified, if exactly one wrapper matches “DftSpecification (*,*)” in memory, the design_name is extracted from the design_name parameter of the DftSpecification wrapper; if more than one wrapper matches, the -design_name must be specified.

- -validate_only

  An optional switch that specifies to only perform the validation of the DftSpecification and to skip Dft element generation and insertion. Using the -no_insertion switch with the -validate_only option disables a few checks such as verifying that the specified parent_instance properties in the Sib, ScanMux and Tdr wrappers actually exist in the design.

- -transcript_insertion_commands

  An optional switch that specifies to enable the transcription of the insertion commands as they are being performed. This option can generate a large number of transcripted commands but you may find it useful to see the instantiation and connection commands created by the process_dft_specification command.

Example

The following example reads a design and a DftSpecification file, and then processes the DftSpecification. The context is changed to the patterns -ijtag context to extract the ICL of the design and generate simulation patterns. This example uses the DftSpecification shown in the example of the ScanMux wrapper documentation. Notice the use of the iNote “tessent_pragma verilog_insert” to inject native Verilog commands into the testbench at specific times to directly monitor the states of internal signals.

```
#-------------- Insert Ijtag Network --------------------
set_context dft -no_rtl
set_tsdb_output_directory scanMux_ex1_outdir
read_verilog ../data/MyCore.v
set_current_design MyCore
read_config_data ../data/ScanMux_ex1.dft_spec
process_dft_specification

#---------------- Extract ICL ---------------------------
set_system_mode setup
set_context patterns -ijtag
set_system_mode analysis
write_icl -out ScanMux_ex1.icl

#---------------- create Simulation Patterns  -----------
set dut "MyCore_ScanMux_ex1_v_ctl.MyCore_inst"
open_pattern_set p1

iNote "iWrite tessent_rtl_tdr_orange_inst.tdr 0b0 and end_in_pause"
```

```
iWrite tessent_rtl_tdr_orange_inst.tdr 0b0
iApply -end_in_pause

iNote "iRead tessent_rtl_tdr_orange_inst.tdr 0b0"
iNote "iWrite tessent_rtl_tdr_orange_inst.tdr 0b1 and end_in_pause"
iRead tessent_rtl_tdr_orange_inst.tdr 0b0
iWrite tessent_rtl_tdr_orange_inst.tdr 0b1
iApply -end_in_pause

iNote "tessent_pragma verilog_insert \$display(\$time, \"ns:\
  measured tessent_rtl_tdr_orange_inst.ijtag_sel = %b\",\
 ${dut}.tessent_rtl_tdr_orange_inst.ijtag_sel);"
iNote "tessent_pragma verilog_insert \$display(\$time, \"ns:\
 measured tessent_rtl_tdr_green_inst.ijtag_sel = %b\",\
 ${dut}.tessent_rtl_tdr_green_inst.ijtag_sel);"
iNote "tessent_pragma verilog_insert \$display(\$time, \"ns:\
 measured tessent_rtl_tdr_red_inst.ijtag_sel = %b\",\
 ${dut}.tessent_rtl_tdr_red_inst.ijtag_sel);"

close_pattern_set

write_patterns ScanMux_ex1.v -ver
```

Related Commands

read_config_data

get_tsdb_output_directory

set_tsdb_output_directory

range_collection

Context: unspecified, all contexts

Mode: all modes

Usage

range_collection ***collection first last***

Description

Returns one or more adjacent elements from a collection and creates a new collection.

The returned collection consists of elements first through last, inclusive. If first is greater than last, this command returns an empty collection.

The base collection remains unchanged.

Arguments

- ***collection***

  A required string that specifies the collection to be searched.

- ***first***

  A required integer that specifies the first index into the collection. Allowed values are from 0 to *sizeof_collection* - 1.

- ***last***

  A required integer that specifies the ending index into the collection. Allowed values are from 0 to *sizeof_collection* - 1. You can also specify the value of the last argument relative to the end of the collection by using "end-<integer>".

Example

The following example returns a collection with the last two elements from $mycoll.

```
range_collection $mycoll end-1 end
```

read_cell_library

Context: unspecified, all contexts

Mode: setup

Usage

read_cell_library ***lib_path*** ... [-force]

Description

Loads one or more cell libraries into the tool.

This command provides functionality equivalent to the -Library tool invocation switch.

You can issue this command multiple times. In case of parsing errors, the tool clears all the library data and returns to Setup mode. After the erroneous file has been corrected and reloaded, the tool reparses all files that were successfully parsed previously.

Arguments

- ***lib_path***

  A required and repeatable string that specifies the names of the files containing the ATPG library descriptions for cell models in your design. You can use wildcards to specify multiple file names.

- -force

  An optional switch to suppress the error message that normally prevents the accidental deletion of previously defined setup information. After you read in a library using this command, you can incrementally issue the command again to read more files. However, once the tool builds the design using set_current_design and you add any configuration information to it (for example, add_clocks or add_scan_chains), executing the read_cell_library command causes the setup information to be discarded. In this case, to prevent configuration information from being discarded unintentionally, the tool requires that you execute the command with the -force switch to indicate that it is acceptable to delete the setup data.

Example

The following example loads two cell libraries:

```
read_cell_library lib1 lib2
```

Related Commands

delete_cell_library
set_cell_library_options
write_cell_library

read_config_data

Context: unspecified, dft, patterns

Mode: all

Usage

read_config_data {*filename_list* | -from_string *string*}
[-in_wrapper *parent_wrapper*]
[-before *before* | -after *after* | -first | -last]
[-replace]

Description

Reads the content of configuration data files or a string into the Tessent Shell environment.

The configuration data file format is currently used for two released features but it will be used to describe many more specifications in the future.

The first usage is to load a dft specification and a defaults specification containing the syntax described in which is used by the and commands.

The second usage is to load the test setup specifications described in "The Configuration Data File for Tessent SiliconInsight Desktop" to allow Tessent SiliconInsight to communicate via hardware adaptors or the SimDUT tool with the design under test (DUT). In this application, Tessent Shell uses the settings in the configuration data file to launch the SiliconInsight Desktop (SID) tester when the launch_sid_tester command is invoked.

Arguments

- *filename_list*

  An optional string that specifies the name of a file or a tcl list of file names. The names can include wildcards (the * character) to allow matching multiple file names with a single pattern.

- -from_string *string*

  An optional option value pair that specifies a string to parse. the string can be contained in a tcl variable or typed between curly brackets as shown in Example 3

- -in_wrapper *parent_wrapper*

  An option value pair that specifies that the read in configuration elements are to be loaded inside a specific wrapper. The *parent_wrapper* can be the complete name of a wrapper relative to the root of the partition or a collection containing a single wrapper element as returned by or " -object". When the -in_wrapper is not specified, the destination parent wrapper is assumed to be the root of the partition unless the -before or -after option is specified.

  If the specified root wrapper is a wrapper of type CSV, you can load a CSV file generated out of Excel™ where the line terminator is the carriage return instead of a semicolon.

- -before *before*

  An optional option value pair that specifies a configuration element before which to the new configuration elements are to be loaded. When the -before option is used with a collection containing a configuration element object, the -in_wrapper option cannot be used as the parent wrapper is extracted from the object.

  When before is a name, it must a name relative to the wrapper specified with the -in_wrapper option. It is a name relative to the root of the partition when the -in_wrapper option is not specified.

  The -before option is mutually exclusive to the -after, -first and -last options. When none of those four option is specified, -last is assumed.

- -after *after*

  An optional option value pair that specifies a configuration element after which the new configuration elements are to be loaded. When the -after option is used with a collection containing a configuration element object, the -in_wrapper option cannot be used as the parent wrapper is extracted from the object.

  When after is a name, it must a name relative to the wrapper specified with the -in_wrapper option. It is a name relative to the root of the partition when the -in_wrapper option is not specified.

  The -after option is mutually exclusive to the -before, -first and -last options. When none of those four option is specified, -last is assumed.

- -first

  An optional option that specifies the new configuration elements are to be loaded before any other element in the parent wrapper.

  The -first option is mutually exclusive to the -before, -after and -last options. When none of those four option is specified, -last is assumed.

- -last

  An optional option that specifies the new configuration elements are to be loaded after all other elements in the parent wrapper.

  The -last option is mutually exclusive to the -before, -after and -first options. When none of those four option is specified, -last is assumed.

- -replace

  An optional options that suppresses the error that is normally generated when loading configuration elements having the same name as an existing element in the destination wrapper. The error only occurs if the name is defined as not repeatable in the metadata. Instead of an error, the existing element is first deleted.

Example

The following example loads the content of the mydesign.dft_spec_rtl file into the Tessent Shell environment.

read_config_data mydesign.dft_spec_rtl

Refer to "Executing an IJTAG Test Pattern" in *Tessent SiliconInsight User's Manual for Tessent Shell* for more usage scenarios.

Example 2

The following example reads a CSV file into a wrapper of type CSV.

```
add_config_element csv(1)
read_config_data data.csv -in_wrapper csv(1)
report_config_data csv(1)
```

Example 3

The following example illustrates the use of the -from_string option. The content of the string was created by the " -wrapper DftSpecification(corea,rtl)/IjtagNetwork/HostScanInterface(custom)" command. The HostScanInterface(custom) was created manually in the Configuration Data window. Because the read_config_data command is inside the callback, the custom HostScanInterface wrapper will automatically inserts itself into the newly generated DftSpecification wrapper when the is called. You could have also used DftSpecification/IjtagNetwork/HostScanInterface to get the available syntax and type it in manually.

```
proc create_dft_specification.post_create (dft_spec_name args} {
  read_config_data -in $dft_spec_name/IjtagNetwork -from_string {
    HostScanInterface(custom) {
      Sib(power_management) {
        DesignInstance(myTDR1) {
        }
        DesignInstance(myTDR2) {
        }
      }
    }
  }
}
```

read_core_descriptions

Context: all contexts

Mode: setup

Usage

read_core_descriptions ***file_names***

Description

Reads the specified Tessent core description (TCD) files.

The Tessent core description file is used to map scan information from one level to the next for running ATPG at the higher level, and to retarget patterns for instances of the associated core.

Arguments

- ***file_names***

  A required, repeatable string that specifies the core description files to be read. The names of the files can contain wildcards. You can define the names of files to read into a Tcl list, and use the name of the Tcl list as the file_names argument.

Example

The "Retargeting Example" in the *Tessent Scan and ATPG User's Manual* demonstrates the use of this command in a design context.

Related Commands

report_core_instances
write_core_description

read_cpf

Context: all contexts

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

Usage

read_cpf ***filename*** [{> | >>} *file_pathname*]

Description

Loads a CPF (Common Power Format) file and removes any previously loaded power data. You can use multiple CPF files by using the native CPF “include” command.

The tools support CPF version 1.0 and 1.1.

Effects of Reading Power Data

Loading power data from a CPF or UPF file has the following effects:

- Simulation of test procedures and scan patterns take into account whether a gate is powered on during simulation.
- The tool runs the Power-Aware Rules (V Rules) when transitioning out of Setup mode.
- Scan insertion restricts scan stitching such that each scan chain includes only scan cells from one power domain.
- Test point sharing is restricted based on power information.
- The power attributes provide access to the power information. The power attributes are:

Data Model	Power Attribute
	is_power_always_on_cell is_power_isolation_cell is_power_level_shifter_cell is_power_retention_cell
, ,	power_domain_name

Power information does not affect dft or analysis in any other way. For example, when creating connections across power domains, the tools do not automatically add isolation cells or level shifter cells.

Arguments

- ***filename***

  A required string that specifies the name of the CPF file.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

The following example loads a CPF file:

read_cpf cpf_file

report_power_data

read_failures

Context: dft -edt, patterns -scan, patterns -scan_diagnosis, patterns -failure_mapping

Mode: analysis

Usage

read_failures ***failure_file*** [-Pattern | -Cycle] [{> | >>} *output_file*]

read_failures ***failure_file*** [-Append]

Description

Checks the specified failure file for correct syntax and semantics and optionally appends a failure file.

By default, this command displays the first 20 pattern mismatches. Use the command to change the number of pattern mismatches that display.

You can also use the read_failures command to display additional information about failed cells within the failure file, or use it to convert a failure file to either pattern-based or cycle-based format. This command supports both, compressed and uncompressed test patterns.

Test patterns must be WGL or STIL format for cycle-based failure files.

When read_failures -append is used, then the order in which the failure files are supplied must match the order in which the multiple patterns sets have been loaded. In the event that one of the failure files is inconsistent with the corresponding test set, an error will be issued and that failure file will not be appended to the previously loaded failure files.

Note

If you omit the -append switch, then the tool overwrites the in-memory failure file.

Tessent Diagnosis performs a basic syntax check during parsing.

Arguments

- ***failure_file***

  A required string that specifies the name of the failure file to read. For failure mapping, this file is a top-level failure file generated as a result of applying top-level patterns created by scan pattern retargeting.

- -Pattern

  An optional switch that displays/writes the failure file in the pattern-based format. Use this switch to convert a cycle-based failure file to a pattern based format or use it to add location information to failed cells within a pattern-based failure file.

- -Cycle

  An optional switch that displays/writes the failure file in the cycle-based format. Use this switch to convert a pattern-based failure file to a cycle-based format or use it to add location information to failed cells within a cycle-based failure file.

- -Append

  An optional switch that appends the *failure_file* to a previously-specified failure file and saves the appended *failure_file* in memory.

  Before appending a failure file, you must issue the read_failures command without the -append switch and, subsequently, issue the read_failures command with the -append switch.

  > *output_file*

  An optional redirection operator and pathname pair used at the end of the argument list to create *or* replace the contents of *output_file*.

- >> *output_file*

  An optional redirection operator and pathname pair used at the end of the argument list to append output to the contents of *output_file*.

Example 1

The following example loads a test pattern source (*1pat.wgl*), reads in a pattern-based failure file (*padding_failures.pat*) and writes out a cycle-based failure file (*pat_cycle.fail*).

```
read_patterns 1pat.wgl
read_failures fail_files/padding_failures.pat -cycle > results/pat_cycle.fail
```

Example 2

In the following command sequence example, the tool appends *failure_file2* to *failure_file1*:

```
read_failures failure_file1

read_failures failure_file2 -append
```

Example 3

In the following command sequence example, the tool appends *failure_file2* to *failure_file1*:

```
read_patterns pat1

read_patterns pat2 -append

read_failures failure_file1

read_failures failure_file2 -append
```

Example 4

The following example shows the *padding_failures.pat* file.

```
chain_test
0  chain5     0   H  L
0  chain5     1   H  L
0  chain5     4   H  L
0  chain5     5   H  L
0  chain5     8   H  L
0  chain5     9   H  L
0  chain5     12  H  L
0  chain5     13  H  L
0  chain5     16  H  L
0  chain5     88  H  L
0  chain5     100 H  L
last_pattern_tested  0
scan_test
0   chain5    2   H  L
0   chain5    4   H  L
0   chain5    6   H  L
0   chain5    8   H  L
0   chain5    9   H  L
0   chain5    11  H  L
0   chain5    12  H  L
0   chain5    13  H  L
0   chain5    28  H  L
0   chain5    100 H  L
last_pattern_tested  2
```

Example 5

In the following command sequence example, the tool appends *failure_file2* to *failure_file1*:

read_failures failure_file1

read_failures failure_file2 -append

Example 6

The following example shows the cycle-based failure file (*pat_cycle.fail*). The cycle-based data is written in columns from left to right: cycle id, pin name, expected value, simulated value, pattern id, chain/PO, cell number, cell path name.

```
format cycle
failures_begin
// chain test
105 dhiraj_so5 H L  // pat 0  chain chain5  cell 0   uUART/reg_MODE0_CLK
106 dhiraj_so5 H L  // pat 0  chain chain5  cell 1   uCNTR/reg_PORT_3_SAMPLE_P1_2_
109 dhiraj_so5 H L  // pat 0  chain chain5  cell 4   uCNTR/reg_PORT_3_SAMPLE_P1_5_
110 dhiraj_so5 H L  // pat 0  chain chain5  cell 5   uINTR/ix546
113 dhiraj_so5 H L  // pat 0  chain chain5  cell 8   uINTR/ix476
114 dhiraj_so5 H L  // pat 0  chain chain5  cell 9   uINTR/ix446
117 dhiraj_so5 H L  // pat 0  chain chain5  cell 12  uINTR/ix356
129 dhiraj_so5 H L  // pat 0  chain chain5  cell 24  uSTM/ix56/SFFR
 ...
// scan test
314 dhiraj_so5 H L  // pat 0  chain chain5  cell 2   uCNTR/reg_PORT_3_SAMPLE_P1_3_
316 dhiraj_so5 H L  // pat 0  chain chain5  cell 4   uCNTR/reg_PORT_3_SAMPLE_P1_5_
318 dhiraj_so5 H L  // pat 0  chain chain5  cell 6   uINTR/ix106
320 dhiraj_so5 H L  // pat 0  chain chain5  cell 8   uINTR/ix476
321 dhiraj_so5 H L  // pat 0  chain chain5  cell 9   uINTR/ix446
323 dhiraj_so5 H L  // pat 0  chain chain5  cell 11  uINTR/ix386
621 dhiraj_so5 H L  // pat 2  chain chain5  cell 101 padding_cycle
failure_buffer_limit_reached all
failures_end
```

Example 7

The following example loads a test pattern source (*1pat.wgl*), reads in a cycle-based failure file (*pat_cycle.fail*) and writes out a pattern-based failure file (*cyc_pat.fail*).

```
read_patterns 1pat.wgl
read_failures fail_files/pat_cycle.fail -pattern > results/cyc_pat.fail
```

Example 8

The following example shows the pattern-based failure file (*cyc_pat.fail*). The pattern-based failure file data is written in columns from left to right: pattern_id, chain/PO_name, cell_number, expected_value, simulated_value, cell_path_name:

```
chain_test
0 chain5   0   H  L  //  uUART/reg_MODE0_CLK
0 chain5   1   H  L  //  uCNTR/reg_PORT_3_SAMPLE_P1_2_
0 chain5   4   H  L  //  uCNTR/reg_PORT_3_SAMPLE_P1_5_
0 chain5   5   H  L  //  uINTR/ix546
0 chain5   8   H  L  //  uINTR/ix476
0 chain5   9   H  L  //  uINTR/ix446
0 chain5   12  H  L  //  uINTR/ix356
0 chain5   13  H  L  //  uINTR/ix326
0 chain5   16  H  L  //  uINTR/ix236
0 chain5   88  H  L  //  padding_cycle
0 chain5   100 H  L  //  padding_cycle
last_pattern_tested  0
scan_test
0 chain5   2   H  L  //  uCNTR/reg_PORT_3_SAMPLE_P1_3_
0 chain5   4   H  L  //  uCNTR/reg_PORT_3_SAMPLE_P1_5_
0 chain5   6   H  L  //  uINTR/ix106
0 chain5   8   H  L  //  uINTR/ix476
0 chain5   9   H  L  //  uINTR/ix446
0 chain5   11  H  L  //  uINTR/ix386
0 chain5   12  H  L  //  uINTR/ix356
0 chain5   13  H  L  //  uINTR/ix326
0 chain5   28  H  L  //  uSTM/reg_WAIT_SYNC/SFFR
0 chain5   100 H  L  //  padding_cycle
last_pattern_tested  2
```

Example 9

The following example loads a test pattern source(*1pat.wgl*), reads in a compressed pattern-based failure file (*fail_file.pat*) and writes out a compressed pattern-based failure file (*pat_2_pat*) that includes cell path names for internal scan chains corresponding to each failing EDT channel.

```
read_patterns 1pat.wgl
read_failures fail_file.pat -pat > results/pat_2_pat
```

Example 10

The following example shows the compressed pattern-based failure file (*fail_file.pat*) loaded into the tool.

```
chain test
   0  edt_channel1  2  H  L
   0  edt_channel1  3  L  H
   0  edt_channel2  0  L  H
   0  edt_channel2  4  H  L
   1  edt_channel1  0  H  L
last_pattern_tested 1
scan test
   0  /x_out[4]  H  L
   0  /x_out[2]  H  L
   0  /y_out[5]  L  H
   0  /y_out[4]  L  H
   0  edt_channel1  0  L  H
   0  edt_channel1  1  H  L
   0  edt_channel1  2  L  H
   1  /x_out[3]  H  L
   1  /x_out[2]  H  L
   1  /x_out[1]  H  L
last_pattern_tested 1
```

Example 11

The following example shows the resulting compressed pattern-based failure file (*pat_2_pat*) output by the tool. Data is written in columns from left to right: pattern_id, channel/PO_name, channel_cycle_id, expected_value, simulated_value, chain---cell_id---cell_path_name. For

compressed patterns, the location of every possible failing cell in the internal scan chains corresponding to each failing EDT channel is listed.

```
chain_test
0  edt_channel1  2  H  L   //  chain1---2---circle_i/reg_x_2_/DF1
                            //  chain2---2---circle_i/reg_f_6_
                            //  chain3---2---circle_i/reg_f_1_
0  edt_channel1  3  L  H   //  chain1---3---circle_i/reg_x_3_/DF1
                            //  chain2---3---circle_i/reg_f_7_
                            //  chain3---3---circle_i/reg_f_2_
0  edt_channel2  0  L  H   //  chain4---0---circle_i/reg_y_2_
                            //  chain5---0---circle_i/reg_x_5_/DF1
0  edt_channel2  4  H  L   //  chain4---4---circle_i/reg_y_6_
                            //  chain5---4---circle_i/reg_y_1_
1  edt_channel1  0  H  L   //  chain1---0---circle_i/reg_x_0_/DF1
                            //  chain2---0---circle_i/reg_f_4_
                            //  chain3---0---circle_i/reg_y_7_
last_pattern_tested  1
scan_test
0  /x_out[4]        H  L   //  PO
0  /x_out[2]        H  L   //  PO
0  /y_out[5]        L  H   //  PO
0  /y_out[4]        L  H   //  PO
0  edt_channel1  0  L  H   //  chain1---0---circle_i/reg_x_0_/DF1
                            //  chain2---0---circle_i/reg_f_4_
                            //  chain3---0---circle_i/reg_y_7_
0  edt_channel1  1  H  L   //  chain1---1---circle_i/reg_x_1_/DF1
                            //  chain2---1---circle_i/reg_f_5_
                            //  chain3---1---circle_i/reg_f_0_
0  edt_channel1  2  L  H   //  chain1---2---circle_i/reg_x_2_/DF1
1  /x_out[3]        H  L   //  PO
1  /x_out[2]        H  L   //  PO
1  /x_out[1]        H  L   //  PO
last_pattern_tested  1
```

Example 12

In the following command sequence example, the tool appends *failure_file2* to *failure_file1*:

read_patterns pat1

read_patterns pat2 -append

read_failures failure_file1

read_failures failure_file2 -append

Example 13

The following example loads the top-level *fail1.top* failure file.

read_failures fail1.top

Description

Loads the path or bridge definitions or user-defined fault models (UDFM) contained in the specified ASCII file into the current tool session.

Bridge Fault Specifics

A bridge fault definition file or output file from the Calibre query server can be loaded with this command. If a syntax error is encountered, the tool issues an error message and stops loading the bridge entries from the file. If a non-syntax error occurs, an error displays but the file continues loading.

After bridge loading completes, the tool displays a summary of all errors and warnings encountered during the load. The summary lists how many bridges could not be mapped and why. For example, a bridge cannot be mapped if it relates to a location within a library cell.

Note

If you define one or more filters using the -Filter switch, the command will load only those bridges that satisfy all specified filter criteria.

For more information on bridge faults and the bridge fault definition file, refer to "Net Pair Identification with Calibre for Bridge Fault Test Patterns" in the *Tessent Scan and ATPG User's Manual*.

Path Delay Specifics

Before you use the tool to create ATPG patterns to detect path delay faults, first place the paths into a properly formatted file. Then use this command to load the file, and the add_faults or read_faults command to add the faults on the specified paths. You must also specify the path delay fault type with the set_fault_type command.

If you return to Setup mode with faults in the path delay fault list, the tool deletes the faults in that list and issues a warning message.

You can use multiple read_fault_sites commands and the results are additive. However, if you do not use the -Force switch, and one of the following conditions is not met when the tool reads in the path data, the tool will issue an error message and terminate the command:

- The path name must not be the same as the name of an existing path.
- The first pin for a path must be a valid launch point. A valid launch point is a primary output of a scan cell state element, or a non-scan state element that satisfies the C1 clock rule.

  If the path includes a clock or state element D-input pin, you must include the state element name in the path (or use the -Force switch). Fail to do so, and the tool will not resolve the path and report an error.
- The last pin for a path must be a valid capture point or a clock input of a scan cell. A valid capture point is a primary output or a data input of a cell that can capture data, whether scanned or not. Examples of invalid capture points would be a latch that is transparent or a memory element that cannot capture data due to a DRC violation, pin constraint, or cell constraint.
- Each pin must have unambiguous fan-in connectivity to the preceding pin, which must not tie to a constant logic value. If the pin fails to have a valid connection with the preceding pin, the tool generates an error and terminates the read_fault_sites command. However, if there is ambiguity in the connectivity, the tool selects a path between the pin and the preceding pin and generates a warning message. You can display the gates in the complete path using the Report Path command.
- Paths cannot propagate through RAM gates, ROM gates, or transparent latches.
- Paths cannot have edge ambiguity during any point in the path. An edge that propagates through XOR gates or the select lines of MUX gates can result in either a rising or falling edge at the gate outputs. You can use inversion parity to avoid edge ambiguity. If this check fails, the tool generates a warning, and you can assume that an edge on the pin is not inverted relative to the preceding pin.
- The condition statements in the path definition file must occur before the first pin statement and before the tool checks for valid pin names and values. The tool does not use the conditions to resolve edge or path ambiguities.

For more information on path delay faults and the path definition file, refer to "Creating a Path Delay Test Set" in the *Tessent Scan and ATPG User's Manual*.

UDFM Specifics

You use this command to load a UDFM definition file. If the tool encounters an error during loading, the tool stops the loading operation and displays a message. When the UDFM file is successfully loaded, the tool displays a summary similar to the following:

```
// UDFM definitions read: Total=1532, Cells=92, Modules=0, Instances=0,
//       No Match=476
```

The summary lists how many UDFM definitions were read from the file and how many of them have been added to the list of fault sites. In the above example, 1532 UDFM definitions are read from the file and 92 cells are added to the list of fault sites. The last value gives you the number of the UDFM definitions that did not match a cell or module in the design. You can use the -Verbose switch to report more detailed warning messages about the UDFM definitions that were not added to the list of fault sites.

For more information about UDFM, refer to "Understanding Test Types and Fault Models" in the *Tessent Scan and ATPG User's Manual*.

Arguments

- ***filename***

  A required repeatable string that specifies the pathname of the path or bridge definition file or the UDFM file to load. This file is an ASCII file that defines the path delay or bridge fault sites or user-defined fault models for ATPG.

- -Force

  An optional switch that specifies continued path reading after the first occurrence of an invalid path. If you do not specify this switch and the command encounters an invalid path, the command generates an error and terminates.

- -Noforce

  An optional switch that specifies for the tool to stop path reading after the first occurrence of an invalid path. This is the default.

- -INSTance *instance_name*...

  An optional switch and repeatable string that causes each fault site in *filename* to be prepended by the *instance_name* string for the reuse of a fault file created prior to the instances being embedded in the current larger design. This switch must occur after the *filename* argument. You can use the asterisk (*) and question mark (?) wildcards to specify the *instance_name* argument, and the wildcard is expanded to all legal instance names. The fault file is loaded for each instance.

- -MODule *module_name*...

  An optional switch and repeatable string that causes each fault site in *filename* to be prepended by *module_name* string for reuse of a fault file created prior to the instances being embedded in the current larger design. This switch must occur after the *filename* argument. You can use the asterisk (*) and question mark (?) wildcards to specify the *module_name* argument, and the wildcard is expanded to all legal instance names whose

actual module name matches the regular expression. The fault file will be loaded for each instance.

- -VErbose

  An optional switch that enables the display of parsing errors and warnings while the path, bridge, or UDFM ASCII file is loaded.

  For bridge entries only, this switch displays a summary of all errors and warnings once bridge entries are loaded. You can specify how these errors and warnings display with one of the following literals:

  All — displays all errors/warnings during loading and a summary report after loading.

  Modules — displays the number of bridges along with the names of the related modules that could not be mapped.

  Instances — displays the number of bridges along with the names of the related modules and instances that could not be mapped.

  By default, only the summary report displays at the conclusion of the load operation.

- -NAmes_ignored

  An optional switch that directs the tool to ignore all bridge names while loading. Use this option to load files having duplicate bridge names in the bridge definition or Calibre query server file, or to save memory.

- -NOEQ

  An optional switch that prevents the loading of equivalent fault sites. This has the advantage of producing the smallest peak memory demand, as well as the smallest final memory demand, for loading.

- -Filter {{DISTance | PARAllel_run | WEIGHT} *operator number*}

  An optional repeatable switch, literal, operator and number quadruplet that filters which bridge entries are loaded based on a specified physical attribute of the bridge. A single blank space is required between each member of the quadruplet. The *number* must be a nonnegative number that applies to the specified attribute in the bridge entry. Attributes include:

  DISTANCE — Real number that specifies the distance attribute in the bridge entry.

  PARALLEL_run — Real number that specifies the parallel_run attribute in the bridge entry.

  WEIGHT — Real number that specifies the weight attribute in the bridge entry.

  The *operator* must be one of the following:

  < less than

  <= less than or equal to

  = equal to

  != not equal to

>= greater than or equal to

> greater than

Due to rounding, it is not advisable to use “=” or “!=” for floating point numbers.

Note

The tool uses the information you provide with the -Filter switch only to determine a subset of bridge entries to load; the values are not used in any other way.

- -Filter TYPE {= | !=} *type_identifier*

  An optional repeatable switch, literal, operator and literal quadruplet that filters which bridge entries are loaded based on the bridge type. A single blank space is required between each member of the quadruplet. Select one of the following literals as the *type_identifier*:

  S2S — Side-to-side

  SW2S — Side-Wide-to-Side: same as S2S but at least one of the two signal lines is a wide metal line.

  S2SOW — Side-to-Side-Over-Wide: same as S2S, but the bridge is located over a wide piece of metal in a layer below.

  C2C — Corner-to-Corner

  V2V — Via-to-Via: an S2S for vias.

  VC2VC — Via-Corner-to-Via-Corner

  EOL — End-of-Line: the end head of a line faces another metal line.

Note

The tool uses the information you provide with the -Filter switch only to determine a subset of bridge entries to load; the values are not used in any other way.

- -Filter LAYER {= | !=} *string*

  An optional repeatable switch, literal, operator and string quadruplet that filters which bridge entries are loaded based on the layer attribute of the bridge. A single blank space is required between each member of the quadruplet. The *string* must be the string value that specifies the layer attribute in the bridge entry.

Note

The tool uses the information you provide with the -Filter switch only to determine a subset of bridge entries to load; the values are not used in any other way.

- -SElect *integer*[%]

  An optional repeatable switch and positive integer pair that specifies to keep the *integer* best bridges of each bridge type. The tool determines the best based on the weight of each bridge after loading all fault locations in all files specified in the command line.

If you include the optional “%” character after the *integer*, it is interpreted as a percentage instead of an absolute number. For example, “-select 20%” directs the tool to retain the best 20% of all bridges after loading, whereas “-select 20” means to keep the twenty best bridges.

Note

A weight attribute must be defined for each bridge in the file for this option to be meaningful. If a weight is not defined for a bridge, it is loaded regardless of this switch.

- > | >> *output_file_name*

  An optional switch that writes the parsing errors, warnings and summary report to the specified file. Use this switch at the end of the command line. Options include:

  > Creates a new or overwrites an existing file.

  >> Appends the output to an existing file.

Example 1

The following path delay example sets up the tool to perform ATPG for the specified path delay faults in the path definition file, */user/design/pathfile*.

First, you must set the fault type and read in the paths:

set_fault_type path_delay
read_fault_sites /user/design/pathfile
report_fault_sites

```
PATH “path0” =
    PIN /I$6/Q + ;
    PIN /I$35/B0 + ;
    PIN /I$35/C0 + ;
    PIN /I$1/I$650/IN + ;
    PIN /I$1/I$650/OUT - ;
    PIN /A_EQ_B + ;
END ;
```

report_faults -all

```
type  code  name_of_path
----  ----  --------------------
//  Warning: No faults reported.
```

Next, add the faults on the paths contained in that file:

add_faults -all
report_faults -all

```
type  code  name_of_path
----  ----  --------------------
  0    UC   path0
  1    UC   path0
```

Now you are ready to perform ATPG on the path delay faults:

create_patterns

The following is an example of a path definition file that contains one path:

```
PATH “path0” =
    PIN /I$6/Q + ;
    PIN /I$35/B0 + ;
    PIN /I$35/C0 + ;
    PIN /I$1/I$650/IN + ;
    PIN /I$1/I$650/OUT - ;
    PIN /A_EQ_B + ;
END ;
```

Example 2

The following bridge fault example sets up the tool to perform ATPG for the bridge fault sites specified in the bridge fault definition file, */user/design/bridgefile*.

First, you must set the fault type and load the bridge sites from the bridge fault definition file:

set_fault_type bridge
read_fault_sites /user/design/bridgefile

```
//
//  Load bridge entries from file "/user/design/bridgefile".
//
//  5 bridge entries were read from file "/user/design/bridgefile".
//  2 bridge entries were skipped due to unknown net name.
//  3 bridge entries were added to the fault site list.
```

report_fault_sites

```
BRIDGE {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U7.BRIDGE";
}
BRIDGE {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U5.BRIDGE";
}
BRIDGE {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U0.BRIDGE";
}
```

Next, add_faults on the sites in the fault site list:

add_faults –all
report_fault_sites

```
BRIDGE {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {UC, UC, UC, UC};
  NAME = "U7.BRIDGE";
```

```
}
BRIDGE {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {UC, UC, UC, UC};
  NAME = "U5.BRIDGE";
}
BRIDGE {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {UC, UC, UC, UC};
  NAME = "U0.BRIDGE";
}
```

Now you are ready to perform ATPG on the bridge faults:

create_patterns

Example 3

The following is an example of a bridge fault definition file that contains one bridge site:

```
VERSION 1.1

BRIDGE {
  NET1="G173";
  NET2="G1296";
  NAME="My_layout.BRIDGE_TYPE1";
  DISTANCE=4.93827e-06 um;
  PARALLEL_run=6.075e-05 um;
  WEIGHT=95
  X_COORDINATE=152500;
  Y_COORDINATE=739500;
  LAYER="metal1";
  TYPE="S2S";
}
```

Example 4

The following example filters bridge entries based on the parallel_run attribute and loads only the bridge entries whose parallel_run attribute is between 7.5e-05 and 8e-05 um into the current fault definition list.

delete_fault_sites -all
read_fault_sites /user/design/bridgefile -filter parallel_run > 7.5e-05 -filter parallel_run < 8e-05

```
//  5 bridge entries were read from file "/user/design/bridgefile".
//  2 bridge entries were skipped due to unknown net name.
//  2 bridge entries were filtered out.
//  1 bridge entry was added to the fault site list.
```

Notice the tool loads only the bridge entries that meet the specified filter criteria, but does not otherwise utilize the attributes. To see the attributes, include the -Attribute switch when you report the fault sites.

Example 5

The following example loads all bridge entries from the *z_bridge_definitions* file and writes loading warnings and errors to the *loading_errors* file:

```
read_fault_sites z_bridge_definitions > loading_errors
//  ... writing to file loading_errors
```

Example 6

In the following example, remember that the read_fault_sites does not actually add the fault to be targeted by ATPG, but only creates a named fault for referencing later. However, will automatically add the loaded faults when issued.

run 1: You create faults via physical extraction for module alu. You complete the run and are satisfied with the block coverage.

```
read_fault_sites alu_bridges_file
create_patterns
```

run 2a: You then embed the alu design from run 1 in a large design as instance alu1. You want to reuse the fault file used in run 1 to define the faults within that particular instance of the new larger design.

```
read_fault_sites alu_bridges_file -instance alu1
```

You want all bridges loaded to be targeted, except for the one in the fault file named *bridge7*. Bridge fault sites must have names in the file and you cannot have used the -names_ignored switch, which throws away the names to save internal storage.

```
delete fault site alu1/bridge7 -name
create_patterns # automatically adds all nondeleted, loaded faults ...
```

run 2b: You embed the alu design 10 times as a different instance and want to reuse the fault file from run 1 to define the faults in each of the 10 instances of module alu.

```
read_fault_sites alu_bridges_file -module alu
```

run 2c: You embed the alu design as inst1 and inst2; because no other instances begin with “nest”, you can use the * wildcard as shown:

```
read_fault_sites alu_bridges_file  -inst inst*
```

In all of these runs, you can issue after loading and deleting fault sites to obtain the desired set. The create_patterns command automatically adds faults at every loaded, undeleted fault site for ATPG to target.

Example 7

The following example loads two UDFM files into the current tool session and displays parsing errors and warnings while loading the second file:

read_fault_sites /home/design/c090_std/c090_std.udfm
read_fault_sites /home/design/c090_io/c090_io.udfm -verbose

```
//  Warning: UDFM - File c090_io.udfm, line 31 - Cell definition u_and2 does
not exist in the circuit.
```

read_faults

Context: dft -edt, patterns -scan

Mode: analysis

Usage

Path Delay/Stuck/Transition/Toggle/Iddq Faults Usage:

read_faults ***filename***
{[-INSTance *instance_name*... | -MODule *module_name*...] [-VERBose] [-GRaybox]
[-DETection {Append | Replace}] }
{[-ALLOW_fault_sampling] | [-RETain] | [-PROtect [-Only] [-Force]] | [-Delete] |
[-DELETE_Equivalent]}
| {[-Merge [-NO_Warnings]]}

Bridge Faults Usage:

read_faults ***filename*** [-RETain]
{{[-INSTance *instance_name*... | -MODule *module_name*...]}
[-GRaybox] } [-DETection {Append | Replace}]

UDFM Faults Usage:

read_faults ***filename*** [-INSTance *instance_name*... | -MODule *module_name*...]
[-VERBose] [-GRaybox][-RETain] [-Force]

Power-Aware Options (applicable only after you have loaded CPF/UPF power data):

[-POWer_check {ON | Off}]

Description

Updates the current fault list with the faults contained in the specified fault file.

The read_faults command affects the current fault population by either adding or removing faults that you specify in an external fault file. Because you must identify the faults before performing ATPG or Fault simulation, this command is useful when you have a large number of faults to identify. The power-aware option loads faults based on the active power mode.

The read_faults command supports the MTFI (Mentor Tessent Fault Information) format. For more information about MTFI, refer to the *Tessent Scan and ATPG User's Manual*.

Path Delay/Stuck/Transition/Toggle/Iddq Faults Specifics

By default, if you do not specify the -Retain switch, the tool initially places all the faults in the fault file into the uncontrolled (UC) fault class. It then analyzes and reclassifies them appropriately.

Note

The filename specified cannot have fault information lines with comments appended to the end of the lines or fault information lines greater than six columns. If it does, the tool will not recognize the line properly and will not add the fault on that line to the fault list.

The format of the fault file data can be either in a three-, four-, or six-column standard format. Regardless of the format, the read_faults command uses only the information in the first, second, and last columns. You may also place comment lines in the file by starting the line with a double slash (//); the tool ignores comment lines. The file follows the format illustrated below:

```
stuck fault_class (cellname) (netname) (ignore) pin_pathname
```

- **stuck** — The first column must be the stuck-at value.
- **fault_class** — The second column must be the fault class value, but only if you use the -Retain option. For detailed information on fault classes, refer to the "Fault Classes" section in the *Tessent Scan and ATPG User's Manual*.
- **cellname** — The third column is the cell name enclosed in parenthesis. When present, this column indicates the type of cell in which the fault resides.
- **netname** — The fourth column is the net name enclosed in parenthesis. When present, this column indicates the net in which the fault resides.
- **ignore** — The fifth column is ignored by both tools.
- **pin_pathname** — The last column must be the pin pathname.

Here is an example of a short fault file that provides just the data the tool uses (as described in the first, second, and last bullets above):

```
// Short fault file example
1 UC /u510/u17/A0
1 UC /u510/u17/Y
0 UU /u510/u17/A1
1 UU /u510/u17/A1
```

When you issue this command, the tool discards all patterns in the current test pattern set unless you issue the "-protect -only" option. See the description of the -Only switch for more information.

Note

When black boxes are present in the design, the read_faults command is unable to load the faults that are inside the black boxes. Instead, the tool discards those faults and issues warning messages. The result is fewer faults loaded into the tool.

Arguments

- ***filename***

  A required string that specifies the name of the ASCII file containing the fault list to load. The command automatically detects when filename is an MTFI file. You can enter only one string.

- -INSTance *instance_name*...

  An optional switch and repeatable string that causes each fault site in *filename* to be prepended by the *instance_name* string for the reuse of a fault file created prior to the

instances being embedded in the current larger design. This switch must occur after the *filename* argument. You can use the asterisk (*) and question mark (?) wildcards to specify the *instance_name* argument, and the wildcard is expanded to all legal instance names. The fault file is loaded for each instance.

- -MODule *module_name...*

  An optional switch and repeatable string that causes each fault site in *filename* to be prepended by *module_name* string for reuse of a fault file created prior to the instances being embedded in the current larger design. This switch must occur after the *filename* argument. You can use the asterisk (*) and question mark (?) wildcards to specify the *module_name* argument, and the wildcard is expanded to all legal instance names whose actual module name matches the regular expression. The fault file will be loaded for each instance.

- -VERBose

  An optional switch that applies only to *-Instance* and *-Module*. Prior to being embedded, top-level IO pins on an instance are faultable sites; after being embedded, they no longer are fault sites. In this case, a summary message states that these faults cannot be loaded due to no longer being a faultable site. If the -Verbose switch is issued, an individual message for each unloadable fault is also issued. By default, this switch is disabled.

- -GRaybox

  An optional switch that causes the instances specified with the -Instance or -Module switch to be treated as gray boxes. When you use the -Graybox switch, you must use either the -Instance or -Module switch.

  When the tool can translate the loading faults to an existing net, the -Graybox switch merges the faults to the internal fault list. When the tool cannot translate a loading fault to an existing net, the tool designates that fault as unlisted and retains its detection status.

  Note that this option does not support reading multiple fault lists for the same instance or module. If your intent is to merge multiple fault lists for a given core, then you must perform the merge during the core-level ATPG run using the “read_faults -merge” command. Note also that you can only merge fault lists of a single fault type. You cannot, for example, merge fault lists for stuck and transition at the core level.

  For more information about using the -Graybox switch and hierarchical fault accounting, refer to “Support for Hierarchical Fault Accounting” in the *Tessent Scan and ATPG User’s Manual*.

- -DETection {Append | Replace }

  An optional switch and literal operand that specifies the operation on the n-detection number of faults in the FaultList data block of the loading MTFI file.

  The Append literal appends the n-detection number stored in the external MTFI file to the n-detection number of the corresponding fault. The append operation caps at the detection limit set by the command. When you use either the -Merge or -Graybox switch, the

"-Detection Append" switch automatically applies. When you use the "-Detection Append" switch, you must also include either the -Merge or -Graybox switch.

The Replace literal replaces the n-detection number of the fault in the internal fault list with the n-detection value of the corresponding fault loaded from the MTFI file. When you use the "-Detection Replace" switch, you must also use the -Retain or -Restore switch.

- -ALLOW_fault_sampling

  An optional switch enables fault sampling when loading faults.

  By default, the read_faults command ignores fault sampling rate data unless you specify this switch. If the fault sampling rate is other than 100%, and you do not specify the -ALLOW_fault_sampling switch, then the tool resets the sampling rate; for subsequent commands, you must re-specify the sampling rate.

Note

The behavior for the -Delete or -DELETE_equiv switches remain unchanged irrespective of whether the you use this switch or not.

- -RETain

  An optional switch that specifies for the tool to retain the fault class of each fault in the fault list.

- -PROtect

  An optional switch that specifies to load all faults from the external fault list file and to protect the detected faults from manipulation by subsequent tool commands.

  The tool assigns the protected faults to class DI. Use this switch when you want the tool to generate tests only for undetected faults (stuck-at, toggle, transition, or IDDQ), yet determine coverage statistics based on all detected faults. This switch does not apply to bridge faults.

Note

Any fault in the tool's current internal fault list that is identical to a protected fault being read in also becomes protected and the tool removes it from the fault list.

Caution

If you use -Protect to turn on fault protection, be sure you no longer need the protection before issuing a subsequent "set_fault_type" command. The command erases all fault information, even the information about protected faults.

-Only

An optional switch that, together with -Protect, specifies to load only the detected faults from the external fault list file and then protect them.

In contrast to other read_faults options, "-protect -only" does not delete the internal pattern set. This is because the option adds and protects faults for which it assumes a

pattern set exists elsewhere (in an external pattern file, for example). It does reset the fault classes, however, because the loaded protected faults also protect any equivalent fault in memory and this will change the coverages. Therefore, be sure to perform a fault simulation of the current pattern set

```
set_system_mode analysis
simulate_patterns
```

-Force

An optional switch that, together with -Protect, specifies for the tool to protect UC faults as well as detected faults from manipulation by subsequent tool commands.

- -Delete

  An optional switch that specifies for the tool to remove all the *filename* faults except the protected faults from the current fault population. To delete protected faults, you must use the command.

- -DELETE_Equivalent

  An optional switch that specifies for the tool to remove all the unprotected *filename* faults from the current fault population within the tool's session, and to remove all the unprotected faults that are equivalent to those in *filename*.

- -Merge

  An optional switch that merges the loaded external faults with the internal fault list. This allows you to combine the fault lists from different ATPG sessions. For example, if you partition your design and run ATPG for each partition, you can get chip-level fault statistics by merging the partition fault lists. Also, for a single design or design partition, you can run ATPG once, then you can target more undetected faults by incrementally running ATPG using different settings and merging fault lists. For more information, see Example 2.

  If a fault being loaded does not exist in the internal fault list, it will be added to the internal fault list.

  If a fault being loaded already exists in the internal fault list, the fault class of the existing fault will be updated to have with the highest priority fault class. For example, if the fault being loaded has a DI class and the matching fault in the internal list has a PT class, then the class of the fault in the internal list will be updated to DI because DI has a higher priority than PT.

  Fault classes are prioritized as follows:

  1. (Highest) Untestable Faults: RE, TI, BL
  2. Detected or Detectable Faults: DR > DS > DF > DI > PT > PU
  3. Aborted or Undetectable Faults: UO > UC > AU > UU

Note

The three untestable fault classes (RE, TI, and BL) have equal priority. It is a conflict to have a fault with more than one untestable fault class. The tool issues a warning message if a fault being loaded has a different untestable fault class than a matching fault in the internal fault list.

-NO_Warnings

An optional switch that suppresses warnings about conflicting untestable fault classes while merging fault lists. If a fault being loaded has a different untestable fault class than a matching fault in the internal fault list, the fault class defined in the internal list will be used.

- -Power_check {ON | Off}

An optional switch and literal that controls the loading of faults in a power-off domain. The default is Off. This switch is applicable only after you have loaded a CPF or UPF file.

ON — A literal that loads the faults on a power-on domain and discards the faults in a power-off domain. Use this option to calculate the overall test coverage, including the faults that are not active in the current active power mode.

Off — A literal that allows all the faults to be loaded without checking the power mode.

Example 1

The following example modifies the current fault population in the tool with the contents of an external fault file, *my_detected_faultlist*. Assume this file is the detected fault list from an earlier session in which patterns were generated and saved to disk along with the detected faults.

The example reads in the detected faults from the fault file and applies protection to them, restricting the tool to generating patterns for only undetected faults. The protection saves the time the tool would otherwise spend duplicating the earlier effort, prevents the tool from reclassifying as AU faults the DS faults from the previous session, and results in a smaller pattern set. The tool will include the protected detected faults when it calculates coverage statistics for the ATPG run. Notice the switches used with the report_faults command to display the protected and unprotected faults.

```
set_system_mode analysis
add_faults -all
read_faults my_detected_faultlist -protect
report_faults -all
report_faults -protected
report_faults -unprotected
create_patterns
```

Example 2

The following example incrementally runs ATPG in two different modes, combining the results of each session, to target additional undetected faults and increase coverage:

Dofile 1

```
// set up design to run ATPG in mode 1
add_scan_groups grp1 testproc
add_scan_chains chain1 grp1 scan_in1 x_out[0]
add_scan_chains chain2 grp1 scan_in2 scan_out1
add_scan_chains chain3 grp1 scan_in3 scan_out2
add_clocks 0 rst
add_clocks 0 clk
add_input_constraints /G -C1

// generate patterns from mode 1 and write out faults
set_system_mode analysis
create_patterns
write_faults mode1.fault -replace
```

Dofile 2

```
// set up design to run ATPG in mode 2
add_scan_groups grp1 testproc
add_scan_chains chain4 grp1 scan_in4 y_out[2]
add_scan_chains chain5 grp1 scan_in5 x_out[5]
add_clocks 0 rst
add_clocks 0 clk
add_input_constraints /G -C1

// generate patterns from mode 2 and write out faults
set_system_mode analysis
read_faults mode1.fault  -merge
reset_au_faults -reclassify
create_patterns
report_statistics
write_faults modes_1_and_2.fault -replace
```

Example 3

The following example illustrates the reuse of a faults file in a case that needs the -instance switch.

Tip: As a reminder, the read_faults command automatically adds the faults as well, assuming that they reference faultable sites. The read_faults command should never be followed by the -All command; that sequence of commands is equivalent to only issuing -All and is never what you intended. If you do not execute the add_faults command and only issue the read_faults command, will only target the faults loaded, which is the desired result.

run 1: The user has an initial design that will eventually be part of a larger design. This initial design has a special subset of all stuck-at faults that are created via nofaulting and/or deleting faults. This fault set needs to be reused when this initial design is reused in the larger design. In this run, we assume that the user works and obtains adequate fault coverage. In order to be able to reuse the faults, the faults are written out to a file *stuck_file*.

run 2: The user has embedded the initial design from run 1into a larger design; the instance of the initial design is named *alu1*. The user now wants to reuse the *stuck_file* fault file (created in run 1) to define the faults within that particular instance (*alu1*) of the new larger design.

Assume that a PI of the alu is named *inA*. Note that this will no longer be a faultable site once embedded (no longer a top level IO pin, or on a model boundary).

```
read_fault_sites stuck_file  -instance alu1 -verbose
// Loading faults  for instance alu1.
// Note: Original fault /inA is no longer a faultable site.
// Could not load alu1/inA
// Note: 1 fault not loaded because no longer a faultable site.
```

The first note in the output is omitted if -Verbose is not issued. The summary line in the second note is always issued to indicate how many were not loaded and added due to no longer being a faultable site, unless none were rejected for that reason.

Assume that a fault in the file *dff_32/Q* was loaded and therefore added, but the user wants to delete that fault. Because it is inside *alu1* once loaded, that must also be used in the reference to unambiguously identify the fault.

```
delete_faults alu1/dff_32/Q -s 0
```

Example 4

The following example modifies the current fault population in the tool with the contents of an external fault file, *my_detected_faultlist*. Assume this file is the detected fault list from an earlier session in which patterns were generated and saved to disk along with the detected faults.

The example reads in the detected faults from the fault file and applies protection to them, restricting the tool to generating patterns for only undetected faults. In addition, the -power_check switch loads the faults on a power-on domain and discards the faults in a power-off domain.

set_system_mode analysis
add_faults -all
read_faults my_detected_faultlist -protect -power_check on

Example 5

The following example add_faults only for instance ELT_edt_aux_I1from the .flt file, and treats that instance as a graybox:

read_faults det1_all.flt -instance ELT_edt_aux_I1 -graybox -verbose

Example 6

The following example updates the faults in the current fault list with the contents of the external UDFM file *c090_std_io.udfm* and displays parsing errors and warnings:

read_faults /home/design/c090_io/c090_std.io.udfm -verbose

```
//  Warning: UDFM - File c090_io.udfm, line 31 - Cell definition u_and2
does not exist in the circuit.
```

read_flat_model

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Usage

read_flat_model ***design_path***

Description

Loads a flattened model into the tool.

The tool can read only one flat model at a time, so you must first use the command before using the read_flat_model command if you previously used this command.

Arguments

- ***design_path***

  A required string that specifies the pathname of a flattened model.

Example

The following example loads a flat model:

```
read_flat_model /u/my_account/designs/model1
```

Related Commands

delete_design
read_verilog
set_current_design
set_design_macros
delete_cell_library
write_flat_model

read_icl

Context: all contexts

Mode: setup

Usage

read_icl **file_name_list** [-bsdl_file *bsdl_file*] [-force]

Description

Reads ICL files into the internal ICL database.

Arguments

- **file_name_list**

  A required list of strings that specifies the names of the ICL files to load. The names of the files can contain wildcards. You can define the list of files to read into a Tcl list and use it to load the files.

  If you have used the command, child modules found instantiated into the currently read modules are searched for in the specified -y directories and the -v files.

- -bsdl_file *bsdl_file*

  An optional option value pair that defines the name of a BSDL file. The option is only needed and used when reading an ICL module containing an AccessLink of STD_1149_1_2001 element. The BSDL file must define an "Entity *entity_name* is" clause where *entity_name* is the one specified in the BSDLEntity property of the AccessLink wrapper. Refer to the "Example" on page 332 for an example of the -bsdl_file usage.

- -force

  An optional switch that suppresses the normal error message that is generated when the read_icl command is issued after the ICL elaboration has happened. With the -force option, the ICL elaboration tree is discarded instead and must be recreated afterward using the set_current_design command.

Return Value

None

Example

In the following example, the first read_icl command reads a set of ICL files specified as multiple strings separated by spaces and surrounded by braces. The second read_icl command reads all files matched by the glob command. The third read_icl command reads all filenames contained within the Tcl list icl_list. In all of these cases, undefined ICL modules found within the modules inside the read ICL files are searched for in the specified icl_src directory.

```
set_design_source -format icl -y icl_src -extension icl
read_icl {chip.icl tdr.icl tap.icl block1.icl block2.icl}
read_icl [glob icl/*.icl]
set icl_list [list chip.icl tdr.icl tap.icl block1.icl block2.icl]
read_icl $icl_list
```

Related Commands

delete_icl_modules

read_modelfile

Context: all contexts

Mode: setup

Usage

read_modelfile {***modelfile_name*** | **-Delete**} ***RAM/ROM_instance_name***

Description

Initializes the specified RAM or ROM gate using the memory states contained in the named modelfile or deletes an earlier modelfile assignment.

The read_modelfile command sets the initial memory states of a RAM or ROM gate using the data that you provide in a modelfile. You can create a modelfile from within the library cell or by using the write_modelfile command. The modelfile must contain initialization data that is in the Mentor Graphics modelfile format.

You specify the RAM or ROM gate that you want to initialize by using its instance name. An error condition occurs if the instance contains multiple RAM/ROM gates. When you issue the command, the flattened model may not be available, so the tool checks for the correctness of the instance name and the modelfile name during rules checking.

You may also initialize memory states of a RAM or ROM gate by specifying the modelfile from within the RAM or ROM model description. To do so, use the **init_file** attribute. When using the init_file attribute, you must specify the full pathname to the initialization file if the file is not located in the directory from where you invoked the tool. For more information about modeling RAMs and ROMs and the init_file attribute, refer to the "RAM and ROM" subsection of the *Tessent Cell Library Manual*.

Modelfile Format

A Mentor Graphics modelfile contains addresses and data. You must present the addresses in hexadecimal or binary format. You can specify a range of addresses such as 0-1f. An address range may contain an asterisk (*) wildcard character. For example, to specify that you want all addresses set to a hexadecimal F, use "* / f;". You cannot use an X in an address.

To add comments to a RAM or ROM initialization file, precede the comment text with two forward slashes (//). For example:

```
0/3;
// here is a comment
1/2;
```

You can present the data in either binary or hexadecimal format; the default is hexadecimal. To specify data in binary format, you must add a '%' to the beginning of the data values. If you use an X within hexadecimal data, all four bits that it represents are Xs. Therefore, to set a single bit to X, use the binary format.

The following two examples are equivalent. The first example shows both an address and its associated data in hexadecimal. The second example shows the same address and data, but the data is now shown in binary.

```
ABCD / 123X;

ABCD /%000100100011XXXX;
```

The following is an example of what an initialization file may look like (range 0-1f):

```
0/ a;
1-f / 5;
10 / 1a;
11-1f / a;
```

Assuming that the ROM has 5 data bits per word, the least that can fit the largest data of "*1a*", following this example, the contents of the memory would be:

```
Word (MS-LS)/  Data (MS-LS)
00000       /  01010       // Created by "0/a;"
00001       /  00101       // Created by "1-f/5;"
00010       /  0101
00011       /  00101       ...
...
01111       /  00101       // Created by "1-f/5;"
10000       /  11010       // Created by "10/1a;"
10001       /  01010       // Created by "11-1f/a;"
10010       /  01010       ...
...
11111       /  01010       // Created by "11-1f/a;"
```

You can use an asterisk (*) for an address range. For example, you could rewrite the previous initialization file as shown here. In this example, the first line assigns the data value "*a*" to the full address range 0-1f. The subsequent lines overwrite the "*a*" data value with the new data values for the specified addresses.

```
* / a;
1-f / 5;
10 / 1a;
```

Making the same assumption as the previous example, following this example, the contents of the memory would be:

```
Word (MS-LS)/  Data (MS-LS)
00000       /  01010    // Created by "*/a;"
00001       /  00101    // Created by "1-f/5”; (replaces 'a' from */a)
00010       /  00101
00011       /  00101    ...
...
01111       /  00101    // Created by "1-f/5”; (replaces 'a' rom */a)"
10000       /  11010    // Created by "10/1a”; (replaces ‘a' from */a)"
10001       /  01010    // Created by "*/a;"
10010       /  01010    ...
...
11111       /  01010    // Caused by "*/a;"
```

Arguments

- ***modelfile_name***

  A string that specifies the pathname to and filename of the modelfile containing the RAM or ROM initialization data in Mentor Graphics modelfile format.

- **-Delete**

  A switch that deletes the modelfile initialization assignment you made previously for the specified RAM or ROM gate instance. Use this switch to undo an incorrectly specified modelfile or instance name (due, for example, to a misspelling or a non-existent modelfile or instance).

Note

If you misspelled the RAM/ROM_instance_name when you first assigned the modelfile, you need to use the same spelling when you delete the assignment. After you remove the incorrect modelfile initialization assignment using the -Delete switch, you can re-issue the read_modelfile command using the corrected modelfile or instance name.

- ***RAM/ROM_instance_name***

  A required string that specifies the instance name of the RAM or ROM gate that you want to initialize, or for which you wish to delete a previous modelfile initialization assignment.

Example 1

The following example initializes the memory states of a RAM gate, then performs an ATPG run:

```
read_modelfile model.ram /p2.ram
set_system_mode analysis
create_patterns
```

If the memory primitive specified in the read_modelfile command did not exist, then the set_system_mode analysis command would result in an error message similar to the following:

```
//  Error : /p2.ram given in an earlier read_modelfile command is NOT a
RAM or ROM primitive.
```

Example 2

The next example fixes the error by using the -Delete switch to remove the incorrect entry from the tool's internal list of RAMs and ROMs to be initialized. The example then re-issues the original command using the correct instance name (assumed to be `/p1.ram`):

```
read_modelfile -delete /p2.ram
read_modelfile model.ram /p1.ram
```

create_initialization_patterns (FS)
set_ram_initialization (FS)
write_modelfile

read_patterns

Context: dft -edt, patterns -scan, patterns -scan_diagnosis,
patterns -scan_retargeting, patterns -failure_mapping

Mode: analysis

Usage

read_patterns ***filename*** [-append]
[-mask_file *mask_filename* [-maskfile_pattern_offset *number*]]
[-preserve_masked_observe_points]

For patterns -scan_retargeting

read_patterns ***file_name*** [-append]

Description

Loads the external pattern set from the specified file.

For pattern retargeting, this command extracts the core name and mode from the pattern file and automatically associates the patterns with the correct core and mode.

This command appends to or replaces the external pattern set, and optionally provides additional observation masking information.

Arguments

- ***filename***

  A required string that specifies a file containing the patterns to be read. This file is typically created with the command. The patterns can be in ASCII, binary, STIL, or WGL test pattern format.

- -append

  An optional switch that appends the new patterns on the existing external pattern set. By default, the command deletes the existing external pattern set and replaces with the new pattern set.

- -mask_file *mask_filename*

  An optional switch that masks certain observation points in external patterns added to the internal pattern set after simulation. This switch enables you to salvage patterns that result in unreliable failures on certain cells at the tester, or that fail verification due to simulation mismatches at a few observation points. Rather than discard failing patterns altogether and accept the accompanying significant reduction in test coverage, you can keep the patterns, use this switch to mask the few problem observation points, and typically see only minimal impact on test coverage.

  The tool obtains the masking information from a text file you create, or from the external patterns read in. In the case of external patterns, the tool applies masks wherever Xs appear in a pattern's unload and measure_po values.

This switch affects the capture values of only those patterns from the external pattern set that the tool has added to the internal pattern set after simulation. Therefore, if you write patterns using “write_patterns -external”, you will not see the masking information from the mask file reflected in the saved patterns; the saved patterns will be exactly the same as the original patterns.

To save a pattern set that incorporates the masking information, use the command to perform a good machine simulation of the external pattern set you specified with “read_patterns -mask_file”. Then use the command *without* the -External switch to write the resulting internal pattern set to a file.

The Mask File

The *mask_filename* specifies a mask file, a text file you create that lists the patterns and locations you want masked. Use the statements and syntax described in to create a mask file. Use one statement per line. Precede comment text with a pair of forward slashes (//). An example mask file follows the table.

The mask file must be in a pattern based format. Most ATE’s return accumulated cycle-based failure data. Use the command to convert cycle-based failure data to pattern based data for the mask file.

Table 7-20. Mask File Statements

Statement	Usage Rules
<location>	Required. Specifies a location to mask or observe. Use as many location statements as you need. List all location statements that specify a pattern index in ascending order. Syntax format depends on the type statement that precedes the location statement, as follows: • If “type mask” or “type observe” precedes the location statement, use one of these two formats: <pattern_index> <primary_output_name> <pattern_index> <chain_name> <cell_ID> • If “type pin_mask” precedes the location statement, use one of the following three formats: <primary_output_name> <chain_name> <chain_output_pin_name> • If “type pin_mask” precedes the location statement, use one of the following three formats: <primary_output_name> <channel_name> <channel_output_pin_name>

Table 7-20. Mask File Statements (cont.)

Statement	Usage Rules
type <value>	Optional. Indicates if the locations specified by subsequent location statements are to be masked (forced to X) or observed. Specify one of the following values: • mask — specifies to mask the locations, for a specific pattern • observe — specifies to observe the locations and mask all others, for a specific pattern • pin_mask — specifies to mask the locations, for *all* patterns. Overrides other type statements that cover the same location. Use as many type statements as you like. By default, the tools assume “type mask” for locations listed before the first type statement. A type statement inserted between two location statements for the same pattern does not take effect until the next different pattern.

Following is an example mask file:

```
//file: my_pattern_mask.ascii
//
// The next 3 lines mask 3 locations in pattern 20.
20 primary_output_12
20 chain2 31
20 chain3 101
// The next line masks 1 location in pattern 25.
25 chain1 120
type observe
// The following 2 lines mask all but the 2 specified locations in
//   pattern 40.
40 chain5 3
40 primary_output_1
// The following type statement takes effect with pattern 61.
type mask
// The next line defines a third observe location for pattern 40.
40 primary_output_2
61 chain4 120
// The next line masks chain5 for all patterns, overriding previous
//   “type observe” for cell 3 of chain 5 for pattern 40, and
//   subsequent “type observe” for cell 99 of chain5 for pattern 65.
type pin_mask
chain5
type observe
// The following line masks all cells in chain5 except cell 99 in
//    pattern 65.
65 chain5 99
```

- -maskfile_pattern_offset *number*

  An optional switch and integer that specifies the pattern offset number for the mask file. By default (when no offset is specified), the pattern in the mask file starts with pattern 0. This switch is useful for reducing the number of pattern files that must be loaded when only a subset need to be masked. For more information, refer to .

- -preserve_masked_observe_points

  An optional switch that allows you to preserve existing masked observation points (scan cell or primary output) in external patterns loaded into the tool. Even if known values are determined after simulation, the tool continues to mask those locations. You can optionally use -mask_file to specify additional observation points to be masked.

Note

When you use the -preserve_masked_observe_points switch, the tool cannot use multiprocessing.

Example 1

The following example demonstrates how to perform fault grading for stuck-at faults using the transition pattern set created previously. Next, the example shows how to perform top-up ATPG.

set _context patterns -scan
set_system_mode analysis
set_fault_type stuck
add_faults -all
read_patterns pattern_transition
simulate_patterns -store_pattern none
create_patterns
write_patterns pattern_topup.stil -stil

Example 2

The following example demonstrates the use of the -maskfile_pattern_offset switch:

Consider the following mask file, named *mask_data.file*:

```
// The next 3 lines mask 3 locations in pattern 20.
20 primary_output_12
20 chain2 31
20 chain3 101
// The next line masks 1 location in pattern 25.
25 chain1 120
```

The following command reads the patterns from a STIL file, reads the above mask file, applying an offset of 400 in the mask file:

read_patterns pats_400_to_599.stil -mask_file mask_data.file -maskfile_pattern_offset 400
simulate_patterns -store_patterns all
write_patterns pats_400_to_599_masked.stil -stil

The result is that patterns 420 and 425 from the STIL file are masked.

Example 3

The "Retargeting Example" in the *Tessent Scan and ATPG User's Manual* demonstrates the use of this command in a design context.

Related Commands

delete_patterns
simulate_patterns
write_patterns

read_procfile

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_retargeting

Mode: analysis

Usage

read_procfile ***proc_filename***
[-Append_or_timing_update | -Replace]

Description

Reads a test procedure file and merges the timing and named capture procedure data it contains with existing data loaded from previous test procedure files.

This command:

- Replaces each existing timeplate with the definition in *proc_filename* for that timeplate.
- Adds any new timeplates defined in *proc_filename*.
- Updates the timing (timeplates) used by existing scan procedures (like test_setup, load_unload and shift) to match the definitions of these procedures in *proc_filename*.
- Merges the named capture procedure (NCP) data in *proc_filename* with NCP data that exists in the tool's database as summarized in .

Table 7-21. Named Capture Procedure Merging Under Different Conditions

Condition	-Append_or_timing_update	-Replace
New NCPs[1] (no NCP in tool has the same name)	Adds new NCPs	Deletes existing NCPs and adds NCPs from *proc_filename*
NCPs of same name exist in tool but are *not* used[2]	Updates existing NCP's timing only	Deletes existing NCPs and adds NCPs from *proc_filename*
NCPs of same name exist in tool and are used[2]	Updates existing NCP's timing only	Invalid; results in an error message.
No NCP in *proc_filename*	Does not alter existing NCPs	Deletes existing NCPs if not used

1. NCP = named capture procedure
2. Used means at least one pattern in the internal or external pattern database uses the NCP.

- Replaces existing clock control definitions of the same name if no test patterns exist. If test patterns exist, an error displays.
- Adds new clock control definitions.

Tip: A good practice is to regularly use the command to write existing procedures and timing data to a test procedure file when you are experimenting with procedures and timing. This allows you to preserve the most up-to-date procedures and timing data in a form you can use in future runs simply by updating the command in your dofile. It also enables you to recover quickly if existing procedures and timing are altered in an undesirable way.

Arguments

- ***proc_filename***

  A required string that specifies the pathname or filename of the test procedure file to read.

- -Append_or_timing_update

  An optional switch that does the following using the data in *proc_filename*:

  - Adds any new NCPs in *proc_filename* to the tool's existing database of NCPs.

    The tool treats as new any NCP in *proc_filename* whose name is not identical to that of an NCP in the tool's existing database. An added NCP is available immediately for ATPG use unless you disable it with the Off command.

  - Update the timing (timeplate) of existing NCPs and other procedures as applicable, without altering them in any other way.

  This is the default.

Note

An NCP in *proc_filename* and its counterpart of the same name in the tool's internal database must have the same event sequence. If their event sequences differ, the command is aborted.

- -Replace

  An optional switch that deletes all existing NCPs in the tool's internal database and replaces them with the NCPs if any in *proc_filename*, provided a current internal or external pattern set does not contain a pattern that uses an existing NCP. If even one existing NCP is used by a pattern, none of them are deleted or replaced. If *proc_filename* does not contain any NCPs, the existing NCPs are deleted and not replaced, provided a current pattern does not use any of them.

Example 1

Test procedure file *orig.proc* defines a simple timeplate as well as a shift, load_unload, and named capture procedure *cap1*. The following example reads in the procedure file, then lists the

current timeplates and procedures stored in the tool's database (for brevity, only the parts of the timeplates and procedures relevant to this example are shown):

add_scan_groups grp1 orig.proc
set_system_mode analysis
report_timeplate

```
timeplate gen_tp1 =
    ...
end;
```

report_procedures

```
 procedure shift =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    ...
 end;

 procedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    ...
 end;

 procedure capture cap1 =
    timeplate gen_tp1 ;
    ...
 end;
```

Example 2

Assume a second test procedure file *update.proc* defines a new timeplate in addition to the original one, revises the shift procedure to use the new timeplate, and defines a new named capture procedure *cap2*. The following example adds the new timeplate, updates the timing in the scan procedures, and adds the new named capture procedure. (The timeplate and procedure changes resulting from the read_procfile command are highlighted in bold in the output of the reporting commands.)

read_procfile update.proc

```
//  The following occurred at line 46 in file update.proc:
//  Procedure shift updates timing in same procedure from file orig.proc.
//     (W14)
//  Loaded new procedure file successfully.
//  1 new capture procedure is added.
//  2 total capture procedures are in the system.
//  2 capture procedures are active for test generation.
```

report_timeplate

```
timeplate gen_tp1 =
    ...
end;

// Timeplate gen_tp1 has an old timeplate
// timeplate gen_tp1 =
```

```
//    ...
// end;

 timeplate gen_tp2 =
    ...
 end;
```

report_procedures

```
 procedure shift =
    scan_group grp1 ;
    timeplate gen_tp2 ;
    ...
 end;

 procedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    ...
 end;

 procedure capture cap1 =
    timeplate gen_tp1 ;
    ...
 end;

 procedure capture cap2 =
    timeplate gen_tp2 ;
    ...
 end;
```

If the read_procfile command of the preceding example had included the -Replace switch, the original NCP would have been replaced with the new one:

read_procfile update.proc -replace

```
//  The following occurred at line 46 in file update.proc:
//  Procedure shift updates timing in same procedure from file orig.proc.
      (W14)
//  Loaded new procedure file successfully.
//  1 new capture procedure is added.
//  1 total capture procedure is in the system.
//  1 capture procedure is active for test generation.
```

report_procedures

```
 procedure shift =
    scan_group grp1 ;
    timeplate gen_tp2 ;
    ...
 end;

 procedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    ...
 end;
```

```
procedure capture cap2 =
   timeplate gen_tp2 ;
   ...
end;
```

read_sdc

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis (dft -edt, patterns -scan, patterns -scan_diagnosis and dft -test_points contexts only)

Usage

read_sdc ***sdc_filename***… [{-Instance *ins_pathname*…} | -Module *module_name*] [{> | >>} *file_pathname*]

Description

Reads false path and multicycle path information from a Synopsys Design Constraint (SDC) file.

Typically you determine false and multicycle paths as part of static timing analysis before running ATPG.

The read_sdc command parses the SDC file, looking for the set_false_path command, the set_multicycle_path command, and other appropriate commands and their arguments. A summary message displays the following information for the relevant commands found in the SDC file:

- Number of false paths — Paths that cannot be activated in the design's functional (at-speed) mode of operation or are untestable due to test constraints you have applied. False paths are derived from the SDC command set_false path, which specifies false path timing (the paths that the STA tool should not evaluate for timing).
- Number of multicycle paths — Paths that have a combined time delay through the path greater than the clock period. False paths are derived from the SDC command set_multicycle_path.
- Number of erroneous paths — False paths that are erroneous (for example, due to misnamed pins).
- Number of case analysis — Conditional false paths, which are false paths along with a Boolean condition. If the associated condition is violated, the effect of the false path is considered. Conditional false paths are derived from the Boolean constraints defined by the SDC command set_case_analysis.
- Number of disable timings — Derived from the SDC command set_disable_timing, which disables the specified timing arcs in a circuit and is used to speed up the runtime of the tool. The set_disable_timing command is virtually equivalent to the set_false_path command.

The SDC commands set_false_path, set_multicycle_path, set_case_analysis, and set_disable_timing are converted into equivalent commands. For example, the following SDC command set_disable_timing:

```
set_disable_timing [get_pins {U1/buf2/Z}]
```

would be translated into the following add_false_paths command:

```
add_false_paths -through U1/buf2/Z
```

The following SDC command set_case_analysis (shown in):

```
set_case_analysis 0 [get_pins {U1/select}]
```

Figure 7-29. Case Analysis Example

would be translated into one conditional false path and one unconditional false path:

```
add_false_paths -through U1 if (U1/select !=0)
```

Note

That is, if U_1/select is not 0, the effect of this false path is considered.

```
add_false_paths -through U1/select
```

When test patterns are simulated during ATPG, the related incorrect capture responses are identified and masked (modified to X) in the resultant test patterns, so they are not the source of simulation mismatches when verified in a timing-based simulator.

The read_sdc command supports the following SDC commands:

- create_clock
- create_generated_clock
- set_case_analysis
- set_clock_groups
- set_disable_timing
- set_false_path
- set_hierarchy_separator
- set_multicycle_path

Be aware that the SDC commands create_clock and create_generated_clock are completely independent of the command add_clocks, which you must still use.

Tip: To avoid problems extracting correct paths from the SDC specifications, write out the SDC file using the PrimeTime static timing analysis tool. Follow the steps outlined in the section "Ensuring the SDC File Contains Valid SDC Information" in the *Tessent Scan and ATPG User's Manual*.

For more information, see "Preventing Pattern Failures Due to Timing Exception Paths," in the *Tessent Scan and ATPG User's Manual*.

Tip: You can use the command to list all of the SDC-defined clocks.

Hybrid TK/LBIST Flow Usage

Reads in the SDC file that describes the false and multicycle paths that should be blocked during LogicBIST.

The scan cells that are the destination of false and multicycle paths will be inferred from the SDC file. Re-circulating muxes with inversion will be inserted on their data input pins to ensure these scan cells do not capture values from timing exception paths. Both false paths and multicycle paths are bound in the same way.

Refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- ***sdc_filename***

  A required, repeatable string that specifies the pathname of one or more SDC files to read.

- -Instance *ins_pathname*

  An optional switch and repeatable string that specifies the pathname(s) of one or more design instances to which the information in *sdc_filename* should be applied. Use this switch when the SDC information in the file was developed at the module (block) level and you now want to read it in and have it properly applied to the specified instance(s) of that module in the netlist.

- -Module *module_name*

  An optional switch and string pair that specifies a design module or ATPG library model, to all instances of which the information should be applied in the specified SDC file(s). Use this switch to specify when the SDC information in the file(s) was developed at the module (block) or ATPG library model level and that it should be applied to every instance of that module or model in the netlist.

- > *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list for creating or replacing the contents of *file_pathname* with a list of any syntax errors encountered while reading the specified SDC file(s).

- >> *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list for appending to the contents of *file_pathname* a list of any syntax errors encountered while reading the specified SDC file(s).

Example 1

The following example reads the file *new_design_sdc* containing one false path definition and one multicycle path definition in Synopsys Design Constraint (SDC) format:

read _sdc new_design_sdc

```
// Reading SDC file new_design_sdc ...
// Finished reading SDC file new_design_sdc.
// read_sdc summary: 1 false path, 1 multicycle path, 0 erroneous paths
```

Tip: If the SDC file contains more than one description of the same path, it is counted only once. Also, the path counts reported in the read_sdc summary apply to the current command only; they are not cumulative counts of the total number of false and multicycle path definitions stored in the internal data base of the tool. To view cumulative data for the path definitions stored within the tool, use the and commands.

Example 2

Continuing with the preceding example, the following example reads another SDC file *latest_design_sdc* containing one false path and three multicycle path definitions, then reports on the false path definitions now stored within the tool:

read_sdc latest_design_sdc

```
// Reading SDC file latest_design_sdc ...
// Finished reading SDC file latest_design_sdc.
// read_sdc summary: 1 false path, 3 multicycle paths, 0 erroneous paths,
//    0 disable timings, 0 case analysis.
```

report _false _paths

```
// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// Total reported false paths = 2
```

Example 3

The SDC files of the two preceding examples could have been read with one command as in the following example:

read_sdc new_design_sdc latest_design_sdc

```
// Reading SDC file new_design_sdc...
// Finished reading SDC file new_design_sdc.
// Reading SDC file latest_design_sdc...
// Finished reading SDC file latest_design_sdc.
// read_sdc summary: 2 false paths, 4 multicycle paths, 0 erroneous paths,
//    0 disable timings, 0 case analyses.
```

Notice the read_sdc summary lists the combined totals for all the files read with the one command.

Example 4

Suppose the SDC file *new_design_sdc* of the preceding example contained two false path definitions instead of one, but one of the definitions was erroneous due to misnamed pins. The following example shows sample messaging when this error is detected in the SDC file:

read _sdc new_design_sdc latest_design_sdc

```
// Reading SDC file new_design_sdc ...
//  Error: Incorrect pin/instance path name(s) in SDC file new_design_sdc,
//     line 5.
//  Error: No gate found for "all_inputs all_outputs"
// Finished reading SDC file new_design_sdc.
// Reading SDC file latest_design_sdc...
// Finished reading SDC file latest_design_sdc.
// read_sdc summary: 3 false paths, 4 multicycle paths, 1 erroneous path,
//    0 disable timings, 0 case analyses.
```

report _false _paths

```
// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// False Path -from B_input -to_clock all_outputs
// Total reported false paths = 3
```

Notice the tool now has the erroneous path definition stored internally. From here, you might want to check for any additional details about this particular definition:

report_false_paths -debug_error -from B_input -to_clock all_outputs

```
// False Path -from B_input -to_clock all_outputs did not find any
//    gate for "B_input all_outputs"
```

Example 5

The following example deletes the erroneous path definition, enters a corrected version of the definition, then confirms there are no remaining errors in any of the false or multicycle path definitions:

delete _false _paths -from B_input -to_clock all_outputs

```
// Deleted 1 false path
```

report_false_paths

```
// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// Total reported false paths = 2
```

add_false_paths -from B -to y[2] y[1] y[0]
report_false_paths

```
// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// False Path -from B -to y[2] y[1] y[0]
// Total reported false paths = 3
```

report_false_paths -error

```
// Total reported false paths = 0
```

Example 6

The following example reads the SDC file *my_block_sdc* and applies the information it contains to instance U1 of the design module *my_block*:

read_sdc my_block_sdc -instance U1

```
// Reading SDC file my_block_sdc ...
// Finished reading SDC file my_block_sdc.
// read_sdc summary: 2 false paths, 0 multicycle paths, 0 erroneous paths
//    0 disable timings, 0 case analyses.
```

Example 7

The following example reads the file of the preceding example and applies the SDC information to instances U2 and U3 of the same design module:

read _sdc my_block_sdc -instance U2 -instance U3

```
// Reading SDC file my_block_sdc ...
// Finished reading SDC file my_block_sdc.
// read_sdc summary: 4 false paths, 0 multicycle paths, 0 erroneous paths
//    0 disable timings, 0 case analyses.
```

Example 8

The following example reads the SDC file *my_block_sdc* and applies the information to every instance of the design module *my_block*:

delete _false _paths -all
read _sdc my_block_sdc -module my_block

```
// Reading SDC file my_block_level_sdc ...
// Finished reading SDC file my_block_level_sdc.
// read_sdc summary: 6 false paths, 0 multicycle paths, 0 erroneous paths
//    0 disable timings, 0 case analyses.
```

Example 9

This example shows that we can read an SDC file in setup mode, transition to analysis mode, and perform X-bounding based on the paths in the SDC file:

read_sdc my_design.sdc

set_system_mode analysis

analyze_xbounding

Related Commands

add_false_paths
report_clocks
report_false_paths
report_multicycle_paths

read_sdf

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

read_sdf ***sdf_filename***...
[-MInimum_delay | -TYpical_delay | -MAximum_delay]
[-Replace | -Append | -INCremental]
[-INstance *hierarchical_instance_name*]

Description

Loads timing data from a Standard Delay Format (IEEE SDF P1497 Draft 0.10) file.

The SDF file is generated by your static timing analysis tool. For complete information, see "Using Timing-Aware ATPG, in the *Tessent Scan and ATPG User's Manual*.

The following limitations apply to the SDF file:

1. For SDF conditional delays, the tool will load them into an internal database. However, only the maximum delay will be used for calculating actual delay. For example:

   (COND b (IOPATH a y (0.21) (0.54)))
   (COND ~b (IOPATH a y (0.27) (0.34)))

   Timing-aware ATPG uses (0.27) (0.54) regardless of the value of b.

2. Only the first two delay value tokens are used.
3. PATHPULSE, PATHPULSEPERCEN, DEVICE, and RETAIN statements are ignored.
4. Delays on Memory and Latch are ignored.
5. Hold time information is ignored.
6. Delays in clock lines are ignored.
7. Latch is assumed to be either a launch or capture point, not as a combinational logic in-between.

Arguments

- -MInimum_delay

  An optional switch that loads only the SDF minimum delay data into the tool.

- -Typical_delay

  An optional switch that loads only the SDF typical delay data into the tool. This is the default.

- -MAximum_delay

  An optional switch that loads only the SDF maximum delay data into the tool.

- -REplace

  An optional switch that removes any previously loaded SDF file information before loading the new SDF file information.

- -APpend

  An optional switch that loads the new SDF file information in addition to the existing information. This is the default. This switch allows you to load multiple SDF files for different modules.

  The tool will issue an error message if the new SDF file contains delay data for a flattened pin that was already defined by a previously loaded SDF file. Use the -INCremental switch if you want to merge all delay data for a flattened pin.

Note

When using this switch, if the selected delay type (minimum, typical or maximum delay) is different from the previous read_sdf command, all previously loaded SDF timing information will be discarded.

- -INCremental

  An optional switch that loads the new SDF file information in addition to the existing information. If the new SDF file contains delay data for a flattened pin that was already defined by a previously loaded SDF file, the new delay data will be cumulated with the previous delay data for that pin. Use the -APpend switch if you do not want to merge any delay data for a flattened pin.

- -INstance *hierarchical_instance_name*

  An optional switch and string pair that specifies the hierarchical instance name to which the SDF file is associated. This option is useful when the SDF file is at the module level.

Examples

The following example reads the typical delay data from the *top_worst.sdf* file:

```
read_sdf top_worst.sdf
```

The following example reads the delay data for multiple modules:

```
read_sdf file1.sdf -maximum_delay -instance /top/module1
read_sdf file2.sdf -maximum_delay -append -instance /top/module2
read_sdf file3.sdf -maximum_delay -append -instance /top/module3
```

Related Commands

report_statistics

set_atpg_timing

read_upf

Context: all contexts

Mode: setup

Usage

read_upf ***filename***

Description

Loads a UPF (Universal Power Format) file and removes any previously loaded power data.

You can load multiple UPF files using the native UPF “load_upf” command.

The tools support UPF version 2.0.

For information about what happens when you load power data, refer to .

Arguments

- ***filename***

  A required string that specifies the name of the UPF file.

Example 1

The following example loads a UPF file:

read_upf upf_file

read_verilog

Context: all contexts

Mode: setup

Usage

read_verilog [***design_path***...] [-verbose] [-force | -no_overwrite] [-blackbox]
[-in_library *logical_lib_name*] [-no_lib_rescan]
[-mfcu] [-format {1995 | 2001 | sv31a | sv2005 | sv2009}]
[-pragma_list *pragma_list*] [-ignore_synthesis_off_sections {On | Off}]
[-vcs_compatibility] [-f *file*]

Description

Reads one or more Verilog files into the specified or default logical library.

The list of available libraries is defined with the , which you only use in rtl context; only one library exists in no_rtl context and it is named “work”.

Note that the MGC_TESSENT and SYNTHESIS design macros are defined by default. For more information, refer to the command description.

Arguments

- ***design_path***

  A required, repeatable string that specifies the name of a Verilog file to load. The names of the files can contain wildcards. You can define the names of files to read into a Tcl list, and use the name of the Tcl list as the design_path. The design_path is optional if you use the -f switch to specify a file that contains at least one design_path.

  If you have used the set_design_sources command, child modules found instantiated into the currently read modules are searched for in the specified -y directories and the -v files.

- -verbose

  An optional switch that reports each file read. For every file read, including the ‘include files, the following messages are returned:

  ```
  // Reading Verilog file filename
  // Finished reading file filename
  ```

- -force

  An optional switch that suppresses the error message that normally prevents the accidental deletion of previously defined setup information. After you read in a design using this command, you can incrementally issue the command again to read more files. However, once the tool builds the design using set_current_design and you add any configuration information to it (for example, add_clocks or add_scan_chains), executing the read_verilog command causes the setup information to be discarded. In this case, to prevent configuration information from being discarded unintentionally, the tool requires that you

execute the command with the -force switch to indicate that it is acceptable to delete the setup data.

- -no_overwrite

  An optional switch that instructs the tool not to replace existing modules. If a module is read that has been read before, the tool reports an error. You can use this switch to avoid overwriting modules or accidentally deleting the design.

- -blackbox

  An optional switch that instructs the tool to ignore the internals of all of the modules specified in the filename argument and extract only the module port definitions and parameters. (Note, however, that the tool parses the internals of the modules to ensure that they contain valid Verilog code.) The resulting module(s) is a blackboxed module. RTL can be read in the no_rtl context when this switch is used. The -blackbox switch is useful mainly to read the interface of an RTL module and be able to instantiate the module in the design using the no_rtl context.

Note

The write_design command does not write out blackboxed modules. If you want to write out the interface view of a module, read the module without the -blackbox option and write it out using the " -interface" option.

- -in_library *logical_lib_name* ("dft -rtl" context only)

  An optional switch that specifies in which logical library the modules are to be read into. The list of possible logical libraries including the default library is defined by the command. If this option is not specified, the modules are read into the default library.

- -no_lib_rescan

  An optional switch that specifies to not rescan the -y directories and the -v files from the beginning each time, but to search for the module beginning with the directory or file in which the previous module was found.

- -mfcu ("dft -rtl" context only)

  An optional switch that applies to SystemVerilog formats which specifies to make global declarations found in one file visible to all SystemVerilog files read in afterward. By default, global declarations found in one file are only visible for elements found later in the same file.

- -format {1995 | 2001 | sv31a | sv2005 | sv2009} ("dft -rtl" context only)

  An optional switch that specifies the format of the input Verilog files. The default is 2001. In a mixed-format situation, you should be sure to re-define your -y and -v library search path when loading modules in a new format because you cannot mixed formats within a single read_verilog command invocation.

  The sv31a is not a standard format but it is the default inside Design Compiler when hdlin_sv_packages is not defined.

- -pragma_list *pragma_list*

  An optional switch and string pair that defines the pragmas for the input files. The pragma_list is a Tcl list containing one or more objects. When this option is not specified, the following list of strings is used as default pragmas: {pragma synthesis mgc_tessent synopsys}. You can overwrite the default pragmas by specifying a new pragma list as shown here:

  read_verilog 1.v -pragma_list {my_pragma1 mgc_tessent}

  You can create an empty list of pragmas by specifying an empty Tcl list as shown here:

  read_verilog 1.v -pragma_list {}

- -ignore_synthesis_off_sections {<u>On</u> | Off}

  An optional switch and literal pair that specifies whether to ignore the synthesis_off sections in the input files. The default is On.

  <u>On</u> — A literal that specifies to ignore synthesis_off sections and to NOT compile the code found within the synthesis_off/on block.

  Off — A literal that specifies to not ignore the synthesis_off sections and to compile the code found within the synthesis_off/on block.

- -vcs_compatibility (“dft -rtl” only)

  An optional switch that specifies to ignore a series of syntax errors allowed by the Synopsys compilers. By default, the tool reports these non-compliant usages as errors.

  When specified, this setting is in effect until the delete_design command is executed. This switch can only be specified in the first execution of the read_verilog command after tool invocation, or after the delete_design command is executed.

- -f *file*

  An optional switch and string pair that specifies an ASCII file that contains pointers to design files. The referenced file is usually generated by another tool, so the -f option allows you to conveniently use the file rather than to reformat the contents of the file into a read_verilog command line. The file can contain only the following elements, one per line:

  - *design_path* — A string that specifies the name of a Verilog file to load.
  - -v *design_path* — A string that specifies the name of a Verilog file to load.
  - -y *dir_path* — A string that specifies a path to a directory that contains Verilog files to load.
  - +libext+*file_extension* — A string that specifies which files in the “-y dir_path” to load. For example: “+libext+.v” loads all .v files.

Example 1

The following example loads all Verilog files matching *.v inside the directory src:

read_verilog src/*.v

Example 2

The following example loads a mixed-language design in the dft context in RTL mode. The results files are written into the edited_design directory.

```
SETUP> set_context dft -rtl

# Specify LIBRARY1 to be mapped into <workdir>/lib1
# work will be mapped to a scratch dir
SETUP> set_logical_design_libraries -logical_names { library1 work}

# Define macro1 for Verilog compilation
SETUP> set_design_macros macro1=5

# Search for Verilog modules in /design/abc/*.v
SETUP> set_design_sources -y /design/abc -extension v

# Read Verilog files
SETUP> read_verilog { top.v core.v } -in_library work -format 2001

# Read VHDL files
SETUP> read_vhdl core1.vhdl  -in_library work -format 1993
SETUP> read_vhdl { core2.vhdl core3.vhdl } -in_library library1 -format 1993

# Set the top
SETUP> set_current_design top

# Enter insertion mode
SETUP> set_system_mode insertion

# Perform design query and manipulation commands
INSERTION> ...

# Write the design
INSERTION> write_design -output_directory edited_design -modified

INSERTION> exit
```

read_vhdl

Context: all contexts

Mode: setup

Usage

read_vhdl [***design_path***...] [-blackbox] [-force | -no_overwrite] [-in_library *logical_lib_name*] [-format {1987 | 1993 | 2002 | 2008}] [-pragma_list *pragma_list*] [-ignore_synthesis_off_sections {On | Off}] [-f *file*]

Description

Loads one or more VHDL files.

You can execute this command with the -force switch but without a design_path argument to clear design setup data only and not read any new files.

Arguments

- ***design_path***

  A required, repeatable string that specifies the name of a VHDL file to load. The names of the files can contain wildcards. You can define the names of files to read into a Tcl list, and use the name of the Tcl list as the design_path. The design_path is optional if you use the -f switch to specify a file that contains at least one design_path.

  The command contains an example that shows a suggested way of loading different VHDL files into different libraries.

- **-blackbox**

  An optional switch that instructs the tool to ignore the internals of all of the modules specified in the filename argument and extract only the module port definitions and parameters. The -blackbox switch is mandatory when in non-RTL mode. The resulting module(s) is a blackboxed module skeleton module. RTL can be read when this switch is used. The -blackbox switch is useful mainly to read the interface of an RTL module to instantiate the module in the design. Although the -blackbox switch supports reading parameterized modules, currently you can only insert an instance of such a module with default values.

  Note

  The write_design command does not write out blackboxed modules.

- -force

  An optional switch that suppresses the error message that normally prevents the accidental deletion of previously defined setup information. After you read in a design using this command, you can incrementally issue the command again to read more files. However, once the tool builds the design using set_current_design and you add any configuration information to it (for example, add_clocks or add_scan_chains), executing the read_vhdl

command causes the setup information to be discarded. In this case, to prevent configuration information from being discarded unintentionally, the tool requires that you execute the command with the -force switch to indicate that it is acceptable to delete the setup data.

- -no_overwrite

  An optional switch that instructs the tool not to replace existing modules. If a module is read that has been read before, the tool reports an error. You can use this switch to avoid overwriting modules or accidentally deleting the design.

- -in_library l*ogical_lib_name* (“dft -rtl” only)

  An optional switch that specifies which logical library the modules are to be read into. The list of possible logical libraries, including the default library, is defined by the command. When this option is not specified, the modules are read into the default library.

- -format {1987 | 1993 | 2002 | 2008}

  An optional switch that specifies the expected format of the input files and which VHDL language constructs can be understood during parsing. The default is 1993.

- -pragma_list *pragma_list*

  An optional switch and string pair that defines the pragmas for the input files. The pragma_list is a Tcl list containing one or more objects. When this option is not specified, the following list of strings is used as default pragmas: {pragma synthesis mgc_tessent synopsys}. You can overwrite the default pragmas by specifying a new pragma list as shown here:

  read_vhdl 1.v -pragma_list {my_pragma1 mgc_tessent}

  You can create an empty list of pragmas by specifying an empty Tcl list as shown here:

  read_vhdl 1.v -pragma_list {}

- -ignore_synthesis_off_sections {<u>On</u> | Off}

  An optional switch and literal pair that specifies whether to ignore the synthesis_off sections in the input files. The default is On.

  <u>On</u> — A literal that specifies to ignore synthesis_off sections and to NOT compile the code found within the synthesis_off/on block.

  Off — A literal that specifies to not ignore the synthesis_off sections and to compile the code found within the synthesis_off/on block.

- -f *file*

  An optional switch and string pair that specifies an ASCII file that contains pointers to design files. The referenced file is usually generated by another tool, so the -f option allows you to conveniently use the file rather than to reformat the contents of the file into a read_vhdl command line. The file can contain only the following elements, one per line:

  - *design_path* — A string that specifies the name of a VHDL file to load.

Example 1

The following example instructs the tool to read only the interface of the modules/entities and ignore the contents:

```
set_context dft -no_rtl
read_verilog  data/pll.v -blackbox
read_vhdl  data/ram_bist.vhd  data/edt_ip*.vhd -blackbox
```

Example 2

The following example loads a mixed-language design in the dft context in RTL mode. The results files are written into the edited_design directory.

```
SETUP> set_context dft -rtl

# Specify LIBRARY1 to be mapped into <workdir>/lib1
# work will be mapped to a scratch dir
SETUP> set_logical_design_libraries -logical_names { library1 work}

# Define macro1 for Verilog compilation
SETUP> set_design_macros macro1=5

# Search for Verilog modules in /design/abc/*.v
SETUP> set_design_sources -y /design/abc -extension v

# Read Verilog files
SETUP> read_verilog { top.v core.v } -in_library work -format 2001

# Read VHDL files
SETUP> read_vhdl core1.vhdl  -in_library work -format 1993
SETUP> read_vhdl { core2.vhdl core3.vhdl } -in_library library1 -format 93

# Set the top
SETUP> set_current_design top

# Enter insertion mode
SETUP> set_system_mode insertion

# Perform design query and manipulation commands
INSERTION> ...

# Write the design
INSERTION> write_design -output_directory edited_design -modified

INSERTION> exit
```

read_visualizer_preferences

Context: unspecified, all contexts

Mode: setup, analysis

Usage

read_visualizer_preferences ***filename***

Description

Reads a DFTVisualizer preferences file and sets current preferences as described in the file.

The read_visualizer_preferences command reads a DFTVisualizer preference file previously saved with the command and updates the current DFTVisualizer session to use the preferences in the specified file.

Tip: When DFTVisualizer first opens in a tool session, it reads the *$HOME/.DftVisualizerrc* preference file if it is present and sets the preferences accordingly; otherwise, it uses hard-coded defaults. Current preference settings are written to this file when you click the Write Prefs button at the bottom of the DFTVisualizer Preferences window.) DFTVisualizer uses the preferences in the default file until overridden by a read_visualizer_preferences command. The last such command entered establishes the preferences DFTVisualizer uses.

Arguments

- ***filename***

  A required string that specifies the name of the preference file to read.

Examples

The following example reads the DFTVisualizer preference file, *my_prefs.dftvis*, and updates the current tool session to use the preferences specified in the file:

```
set_system_mode analysis
read_visualizer_preferences my_prefs.dftvis
```

Related Commands

write_visualizer_preferences

read_window_contents

Context: all contexts

Mode: setup, analysis

Usage

read_window_contents ***file_pathname*** **-display** ***window_name*** [-format *format*]

DFTVisualizer Menu Path:
File > Save As

Description

Reads the contents of the specified file into a DFTVisualizer window.

The file specified by the file_pathname argument must be in a supported format as described in the -format argument description.

The window specified by the window_name argument must be visible and not minimized.

Arguments

- ***file_pathname***

  A required string that specifies the pathname of the file that is to be read into a DFTVisualizer window. If the file is to be read into a Debug or Design window, the file must be in the Mentor Graphics Tessent schematic format.

- **-display** ***window_name***

  A required switch and literal pair that specifies the DFTVisualizer window into which the file_pathname content is to be read. Select the window name from the following list:

  DEBug
  A literal that specifies the Debug window. This is the default.

  DESign
  A literal that specifies the Design window.

  Text_editor
  A literal that specifies the Text Editor window.

- -format *format*

  An optional switch and literal pair that specify the format of the file to be read. The file displays in the Text Editor window with appropriate highlighting and formatting. Format options include:

  TEXt
  A literal that specifies an ASCII text format. This is the default.

  Verilog
  A literal that specifies the Verilog format.

  VHdl
  A literal that specifies the VHDL format.

TESt_procedure
A literal that specifies the Test Procedure format.

Dofile
A literal that specifies the Dofile format.

register_attribute

Context: unspecified, all contexts

Mode: all modes

Usage

register_attribute **-name** ***attribute_name*** **-value_type** ***data_type*** **-default** ***default_value*** [-min *min_value*] [-max *max_value*] [-enum *enum_values]* **-object_types** ***type_list*** [-dense] [-description *description_text*] [-show_default]

Description

Registers a new user-defined attribute.

This command allows you to define new attributes for object types available in Tessent Shell. After registration, the value of the new attribute can be set and retrieved on objects such as a module or an instance.

If an attribute with the same name already exists for the specified object type, or if an object type in type_list does not exist, or if a data type is invalid for one of the options, an error message displays.

If you want an attribute set on a module to be visible (inherited) on the instances of the module, register the attribute only on the *module* object type and not on the instance object type. The same is true for inheritance between ports and pins and between nets and pins. The following exceptions to this inheritance rule exist for Boolean attributes:

- For Boolean attributes registered on module and instance object types — When the value is queried on an instance and it is the default value (usually false), the value from the corresponding module is returned.
- For Boolean attributes registered on port and pin object types — When the value is queried on a pin and it is the default value (usually false), the value from the corresponding port is returned.

Arguments

- **-name** ***attribute_name***

  A required switch and value pair that specifies the name of the attribute to register. An attribute name must begin with an alpha character and must only contains alpha-numeric characters and the underscore (_).

- **-value_type** ***data_type***

  A required switch and value pair that specifies the attribute's data type. The value_type argument is an enumerated list with the following possible values: Boolean, integer, double, string, enum. For more information on these data types, see “.”

- **-default *default_value***

  A required switch and value pair that specifies the default value for the attribute when the attribute is not explicitly set. This pair is required for attributes with non-Boolean data types only; it cannot be set for attributes whose data type is Boolean. Attributes with a data type of Boolean automatically default to false.

- -min *min_value*

  An optional switch and value pair that specifies the minimum value for the attribute. When this argument is specified, the value of the attribute is only accepted if it is greater than or equal to min_value. This argument is only valid for attributes whose data type is integer or double. For more information on these data types, see “.”

- -max *max_value*

  An optional switch and value pair that specifies the maximum value for the attribute. When this argument is specified, the value of the attribute is only accepted if it is less than or equal to max_value. This argument is only valid for attributes whose data type is integer or double. For more information on these data types, see “.”

- -enum *enum_values*

  An optional switch and value pair that specifies a Tcl list of possible values for the attribute. The enum_values value can only be set to one value in the list. This argument is only valid for attributes whose data type is string.

- **-object_types *type_list***

  A required switch and value pair that specifies the object type to which the new attribute can be assigned. The type_list string is a Tcl list that contains one or more of the following object types: module, instance, port, pin, or net. If an object type is not included in the type_list, the new attribute cannot be assigned to that object_type.

  Extra data types will be available in subsequent releases and the type_list will be augmented as they become available.

- -dense

  An optional Boolean switch that specifies the storage type for the attribute.

  When not specified — Specifies *sparse* storage which only stores values for objects that have an attribute value set to something different than the default value. This option is a good choice when many of the attributes on an object are set to their default value because it saves memory. However, indexing and searching can be slower and end up consuming more memory if the number of objects having the attribute specified is more than 10% of the object count.

  When specified — Specifies *dense* storage which creates an entry for each object and its attribute value. This option is a good choice when many objects with the same attribute have a distributed set of attribute values because it enables faster indexing and searching. However, it has a higher memory usage when less than 10% of the objects have the attribute specified.

- -description description_text

  An optional switch and value pair that specifies to store a string describing the attribute. The description is displayed when the report_attributes command is executed for the attribute. The description_text argument is a quoted string that can be formatted as a Tcl string which includes support for escaped characters such as “\n” and “\t”.

- -show_default

  An optional Boolean switch that specifies how the registered attribute is handled by the get_attribute_list and report_attributes commands.

  false — If set to false during registration, the get_attribute_list obj_spec and report_attribute obj_spec command executions list or report attributes found on any object within obj_spec *only if* the attribute is set to a non default value.

  true — If set to true, the attribute is always listed or reported if obj_spec contains at least one object of the type for which the attribute is registered for.

Example 1

The following example registers the attribute named speed with a range of possible values equal to or greater than 100 and less than or equal to 500; assigns a default value of 200 to it; sets it as an attribute for the pin design object type only. Notice how the Tcl append command is used to allow typing the string on multiple lines without inserting extra white spaces into the string.

```
set     desc “This attribute is used to hold the target frequency the pin is \n”
appenddesc “allowed to have.\n”
appenddesc “The allowed frequency range of 100 to 500 was chosen to match\n”
appenddesc “the technology spec.”

register_attribute -name speed \
        -value_type integer \
        -default 200 \
        -min 100 \
        -max 500 \
        -object_types pin \
        -description$desc
```

Example 2

The following example defines the attribute named added_by as a string with a value of either “John”, “Patrick”, or “Susan” with a default of John, and a design object type of module:

```
register_attribute -name added_by \
        -value_type string \
        -default John \
        -enum {John Patrick Susan} \
        -object_types net
```

[-string_option *string_option*]
[-real_option *real_option*]
[-integer_value i*nteger_value*]
[-string_value *string_value*]
[-real_value *real_value*]

Description

Registers a Tcl command and makes it available in the global name space.

The registered command appears as a normal tool command with proper option parsing and online help messages. The body of the registered command is implemented in a Tcl proc referenced by the -tcl_proc option. After the options are validated, they are packaged into a Tcl list of option-value pairs that are packed into a Tcl array for easy random access as shown in .

You control the availability of the newly registered command using the -context_list and -system_mode_list options.

Arguments

- ***command_name***

  A required string that specifies the name of the command to register. Because the command will exist in the global name space, its name must be unique so that it does not collide with other already registered commands. You can unregister any registered Tcl command using until you execute the lock_current_registration command. After you execute , all already registered commands and attributes are locked and can no longer be modified.

All commands loaded with an automated plugin mechanism are locked before the interactive shell is released to the user. Example 2 explains how to initially debug your commands interactively when it is still possible to unregister them, and then shows you how to package them into a plugin directory which is automatically loaded at tool invocation. For more information on plugins, see the command.

- -syntax_bnf ***syntax_bnf***

  A required switch and string value pair that specifies the grammar rules of your command using simple Backus-Naur Form (BNF). You should place the syntax_bnf string in braces to avoid needing to escape square brackets which are used to express that an option or value is optional. You should use parentheses to group options that are exclusive to others. You can use the | symbol to denote exclusivity of options. BNF uses the symbols you defined when declaring the *option and *value arguments; the symbols must always be enclosed in <> characters.

  The following example defines five arguments; the first two are required and the last three are optional. The fifth argument is mutually exclusive of the third and fourth arguments. An argument is repeatable if its tag is declared with an * as its last character.

  { <arg1> <arg2> ([arg3] [arg4]) | [arg5] }

- **-tcl_proc *tcl_proc***

  A required switch and string pair that specifies the name, including its namespace, of the Tcl proc this command will call. To facilitate packaging the new command as a plugin that is automatically loaded into local namespaces, you should specify tcl_proc using the following format: [namespace current]::*proc_name*. This format ensures that the registered Tcl command always knows where to look for the Tcl proc regardless of which namespace the command is evaluated in.

  For easy interactive debugging that can be easily deployed as a plugin, you should package both your Tcl proc and the register_tcl_command into a single file and surround it with a namespace eval *name_space* {} wrapper. Do not put :: in front of the specified name_space string so that this namespace string will be automatically appended to the one automatically created for all plugins. See the examples for more information on how to do this.

- **-context_list *context_list***

  A required switch and string pair that specifies a Tcl list of contexts the command is enabled in. Each element of the Tcl list is a context with an optional sub-context option as shown here:

  ```
  -context_list {{dft} {patterns -ijtag}}
  ```

  The available contexts are: dft, patterns. The available sub-contexts are those described for each context on the command reference page.

- **-system_mode_list *system_mode_list***

  A required switch and string pair that specifies a Tcl list of system modes the command is to be enabled in. The available modes are: setup, analysis, and insertion.

- -resource_list *resource_list*

  An optional switch and string pair that specifies the list of resources required for the command to be available; if any of the specified resources is not available, the command is not available. The resource_list argument is a Tcl list of strings that identify the resources required. Possible values are:

  design_is_elaborated

  Used to check that the hierarchical data model has been created using the set_current_design command.

  design_modules_exist

  Used to check that at least one Verilog or VHDL module exists in memory and can be accessed using the get_modules command.

  flat_model_exists

  Used to check that the flat data model is available. The flat data model was created by either the create_flat_model command or by the “set_system_mode analysis” command.

  icl_is_elaborated

  Used to check that the ICL hierarchical data model exists. It exists after the set_current_design command if an ICL module corresponding to the current design existed prior to issuing the command. It also exists in the analysis mode if the top-level ICL module was successfully extracted with ICL extract.

  icl_modules_exist

  Used to check that at least one ICL module exists in memory and can be accessed using the get_icl_modules command.

  rtl_mode_enabled

  Used to check that the -rtl option switch was used when specifying the context and that read-in Verilog and VHDL files can contain RTL constructs.

- -extra_help *extra_help*

  An optional switch and string pair that enables you to define a multi-line help paragraph that is displayed at the bottom of the online help. You can use \n to break your strings into multiple lines. The easiest way to create a multi-line help string is to construct it line by line as shown here:

  ```
  set extra_help “This is line1\n”
  append extra_help “and this is line 2\n”
  append extra_help “and this the last line.”
  register_tcl_command -extra_help “$extra_help” ...
  ```

- -integer_list_option *integer_list_option*

  An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of integers. The integer_list_option_list string is a Tcl list with three required elements and five optional elements as shown here:

```
{{<symbol>} {-option_name} {tag} [{description_string}] [{range}]
[{enum_list}] [{<help_symbol>}][{<visibility>}]}
```

<symbol> — The first element of the list is required. It defines a unique symbol for the argument that you use in the -syntax_bnf syntax_bnf string to refer to it and it also displays in the online help description. The symbol string must always begin with a < character and end with a > character.

-option_name — The second element of the list is required. It defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name <symbol>”.

tag — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an * character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (i.e. tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

```
{{range,0}{value1}{range,1}{value2}{range,2}{value3}}
```

description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

range — The fifth element is optional. It consists of one or two integers specifying the minimum and maximum value for the argument. When the range is not specified or is specified as empty, the smallest allowed value is a MIN_INT. When the second integer is not specified, the largest allowed value is MAX_INT. If you need to specify the enum_list element but do not want to limit the range, specify this fifth element as empty using an empty brace pair.

enum_list — The sixth element is optional. It allows you to specify strings as allowed values. For example, you may want to define an option that allows a positive integer or the literal “last”. This is achieved by using a minimum value of 0 and an enum string called “last”.

<help_symbol> — The seventh element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf string. For example, the help message of the get_instances command shows “[-parent_of_instances <instance_objects> | -below_instances <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eight element.

visibility — The eighth element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the

option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- -string_list_option *string_list_option*

  An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of strings. The string_list_option is a Tcl list with three mandatory elements and four optional elements as shown here:

  ```
  {{<symbol>} {-option_name} {tag} [{description_string}] [{enum_list}]
  [{<help_symbol>}] [{<visibility>}]}
  ```

  <symbol> — The first element of the list is required. It defines a unique symbol for the argument that you use in the -syntax_bnf syntax_bnf string to refer to it and it also displays in the online help description. The symbol string must always begin with a < character and end with a > character.

  -option_name — The second element of the list is required. It defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name <symbol>”.

  tag — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an * character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (i.e. tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

  ```
  {{name,0}{value1}{name,1}{value2}{name,2}{value3}}
  ```

  description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

  enum_list — The fifth element is optional. It allows you to specify strings as allowed values. When omitted or specified as an null string, the string_list_option allows any string values.

  <help_symbol> — The sixth element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf string. For example, the help message of the get_instances command shows “[-parent_of_instances <instance_objects> | -below_instances <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eight element.

  visibility — The seventh element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the

option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- -real_list_option *real_list_option*

  An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of real numbers. The real_list_option is a Tcl list with three required elements and five optional elements as shown here:

  ```
  {{<symbol>} {-option_name} {tag} [{description_string}] [{range}]
  [{enum_list}] [{<help_symbol>}] [{<visibility>}]}
  ```

  <symbol> — The first element of the list is required. It defines a unique symbol for the argument that you use in the -syntax_bnf syntax_bnf string to refer to it and it also displays in the online help description. The symbol string must always begin with a < character and end with a > character.

  -option_name — The second element of the list is required. It defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name <symbol>”.

  tag — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an * character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (i.e. tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

  ```
  {{range,0}{value1}{range,1}{value2}{range,2}{value3}}
  ```

  description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

  range — The fifth element is optional. It consists of one or two integers specifying the minimum and maximum value for the argument. When the range is not specified or is specified as empty, the smallest allowed value is a MIN_DOUBLE. When the second interger is not specified, the largest allowed value is MAX_DOUBLE. If you need to specify the enum_list element but do not want to limit the range, specify this fifth element as empty using an empty brace pair.

  enum_list — The sixth element is optional. It allows you to specify strings as allowed values. For example, you may want to define an option that allows a positive integer or the literal “last”. This is achieved by using a minimum value of 0 and an enum string called “last”.

  <help_symbol> — The seventh element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf

string. For example, the help message of the get_instances command shows “[-parent_of_instances <instance_objects> | -below_instances <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eight element.

visibility — The eighth element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- -boolean_option *boolean_option*

  An optional switch and string pair that defines an argument that is an option without a value. The boolean_option string is a Tcl list with three required elements and two optional elements as shown here:

  ```
  {{<symbol>} {-option_name} {tag} [{description_string}] [{<visibility>}]}
  ```

  <symbol> — The first element of the list is required and defines a unique symbol for the argument. You use this element in the -syntax_bnf syntax_bnf string to refer to it. The symbol string must always begin with a < character and end with a > character.

  -option_name — The second element of the list is required and defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name”.

  tag — The third element of the list is required and defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc.

  description_string — The forth element is optional and can be used to define a one-line description for the argument that displays in the online help.

  visibility — The fifth element is optional and can be used to specify whether the option is included in the help message. You specify a null string "" if you want the option to show up in the help message and you specify the string "hidden" if you want the option to be hidden.

- -integer_list_value *integer_list_value*

  An optional switch and string pair that is identical to the -integer_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

  The integer_list_value string is a Tcl list with two required elements and five optional elements. This string has exactly the same definition as the integer_list_option string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with an * character because only options can be defined as repeatable.

  ```
  {{<symbol>} {tag} [{description_string}] [{range}] [{enum_list}]
  [{<help_symbol>}] [{<visibility>}]}
  ```

- -string_list_value *string_list_value*

  An optional switch and string pair that is identical to the -string_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

The string_list_value string is a Tcl list with two required elements and four optional elements. This string has exactly the same meaning as the string_list_option string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with an * character as only options can be defined as repeatable.

```
{{<symbol>} {tag} [{description_string}] [{enum_list}] [{<help_symbol>}]
[{<visibility>}]}
```

- -real_list_value *real_list_value*

  An optional switch and string pair that is identical to the -real_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

  The real_list_value string is a Tcl list with two required elements and five optional elements. This string has exactly the same meaning as the real_list_option string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with a * as only options can be defined as repeatable.

```
{{<symbol>} {tag} [{description_string}] [{range}] [{enum_list}]
[{<help_symbol>}] [{<visibility>}]}
```

- -integer_option *integer_option*

  An optional switch and string pair that is identical to the -integer_list_option switch and string pair except that only a single integer is allowed as the value as opposed to a Tcl list of integers.

- -string_option *integer_option*

  An optional switch and string pair that is identical to the -string_list_option switch and string pair except that only a single string is allowed as the value as opposed to a Tcl list of strings.

- -real_option *real_option*

  An optional switch and string pair that is identical to the -real_list_option switch and string pair except that only a single real is allowed as the value as opposed to a Tcl list of real numbers.

- -integer_value *integer_value*

  An optional switch and string pair that is identical to the -integer_list_value switch and string pair except that only a single integer is allowed as the value as opposed to a Tcl list of integers.

- -string_value *string_value*

  An optional switch and string pair that is identical to the string_list_value switch and string pair except that only a single string is allowed as the value as opposed to a Tcl list of strings.

- -real_value *real_value*

  An optional switch and string pair that is identical to the real_list_value switch and string pair except that only a single real is allowed as the value as opposed to a Tcl list of reals.

Example 1

The following example defines a simple proc call “example” that displays the arguments it receives. The register_tcl_command defines a command called “example” that accepts a repeatable integer list option, a non-repeatable string option, and a string value. Notice that the registered command will be located in the global namespace and the Tcl proc that it calls is located in the ExampleCommands:: namespace so the two identical names do not collide.

```
namespace eval ExampleCommands {
   proc example {args} {
      puts $args
   }

   register_tcl_command example \
      -string_value {{<chain_name>} {chain}} \
      -string_option { {<label>} {-label} {label} } \
      -integer_list_option { {<range>} {-range} {range*} } \
      -syntax_bnf {<chain_name> [<label>] [<range>]} \
      -context_list {dft patterns} \
      -system_mode_list {analysis} \
      -tcl_proc “[namespace current]::example”
}
```

Example 2

The following example defines a wrapper Tcl proc that is used to call the intercept_with_cell procedure described in of the get_dft_cell command. The code is surrounded in a namespace eval block which puts the intercept_with_cell_wrapper proc in that name space and avoids polluting the global namespace with the Tcl procs when sourcing it. The [namespace current] command, used with the register_tcl_command -tcl_proc option, ensures the tool knows to search in the correct name space. It also ensures that the registered Tcl command in the global namespace does not collide with the Tcl proc of the same name.

After you verify that your registered commands and/or attributes work correctly, you can make them into a *plugin* directory that Tessent Shell automatically loads during initialization. To create the plugin directory, simply place your files in a directory called <plugin>/tcl_modules/<MySpace> where <plugin> and <MySpace> are arbitrary directory names. Set a TESSENT_PLUGIN_PATH environment variable to point to the <plugin> directory and any files with a .tcl extension found inside <plugin>/tcl_modules/<MySpace> will be evaluated into the Tcl namespace ::tcl_modules::<MySpace>. Just like the PATH environment variable, you can specify more than one search location by separating multiple directory names with a colon. A utility command initialize_module is used to load all files ending with .tcl found inside a local directory having the exact same name as the name space.

In the example below, the namespace is called InterceptWithCell which means that initialize_module will source all files matching *./InterceptWithCell/*.tcl*. The advantage of using the initialize_command is that the Tcl proc is only loaded the first time it is needed.

If you name your <plugin> directory name “tessent_plugin” and place it one level above the bin directory of Tessent Shell, the directory will be automatically loaded unless the environment variable TESSENT_PLUGIN_IGNORE_DEFAULT_PATH is defined. Once the plugins are loaded, the command is issued so that they cannot be unregistered accidentally.

```
namespace eval InterceptWithCell {
   proc intercept_with_cell_wrapper {args} {
      initialize_module
      intercept_with_cell_body {*}$args
}
set extra_help "Command accepts a pin, port, or net object as first"
append extra_help "argument. It is intercepted with cell returned by \n"
append extra_help "get_dft_cell <cell_function_name>."

set cell_list "One of mux, clock_mux, and, clock_and, clock_or,"
append cell_list "buffer, clock_buffer, or inverter."

set bnf {<node> <function_name> [<input2_source>] [<select_source>] }
append bnf {[<level>] [<reset_intercept_list>]}

register_tcl_command intercept_with_cell \
   -context_list {dft} \
   -system_mode_list {insertion} \
   -resource_list {design_is_elaborated} \
   -extra_help $extra_help \
   -string_value {"<node>" {node} {} } \
   -string_option [list "<function_name>" "-cell_function_name" \
      {cell_sel} $cell_list {mux clock_mux and clock_and or \
      clock_or buffer clock_buffer inverter}] \
   -string_option {"<input2_source>" "-input2" {input2} {}} \
   -string_option {"<select_source>" "-select" {select} {}} \
   -integer_option {"<level>" "-cascading_level" {level} {} {1 9}} \
   -boolean_option {"<reset_intercept_list>" "-reset_intercept_list" \
      {clear}} \
   -syntax_bnf "$bnf" \
   -visibility hidden \
   -transcript tool_command \
   -tcl_proc "[namespace current]::intercept_with_cell_wrapper master"
}
```

The online help for the registered command is shown here:

```
INSERTION> help intercept_with_cell
   intercept_with_cell <node> -cell_function_name <function_name>
            [-input2 <input2_source>] [-select <select_source>]
            [-cascading_level <level>] [-reset_intercept_list]

DESCRIPTION
   -cell_function_name: One of mux, clock_mux, and, clock_and, or,
clock_or, buffer, clock_buffer

Command accepts a pin, port, or net object as first
argument.It is intercepted with cell returned by
get_dft_cell <cell_function_name>.
```

remove_from_collection

Context: unspecified, all contexts

Mode: all modes

Usage

remove_from_collection ***base_collection obj_spec***

Description

Removes objects found in obj_spec from a collection, resulting in a new collection.

The base_collection remains unchanged.

If obj_spec is a null collection, the resulting collection is a copy of the base collection. If everything in base_collection is included in obj_spec, the result is an empty collection.

Arguments

- ***base_collection***

  A required value that specifies the base collection from which objects within obj_spec are to be removed.

- ***obj_spec***

  A required value that specifies an object name, a Tcl list of object names, or a collection of objects.

Example

The following example creates a collection of all input and inout ports minus the port called CLK.

set data_in [remove_from_collection [get_ports -direction input inout] CLK]

```
{"in1", "in2"}
```

rename_instance

Context: all contexts

Mode: insertion

Usage

rename_instance ***obj_spec*** **-new_leaf_name** ***leaf_inst_name*** [-silent]

Description

Renames the leaf name of an instance.

This command returns a collection containing the renamed instance.

If the instance within obj_spec does not exist or if an object already exists with the same leaf_inst_name within the parent_instance, the tool generates an error. You can use the -silent switch to specify to not generate an error message and ignore the renaming request in which case the command returns a null collection.

Arguments

- ***obj_spec***

  A required value that specifies a single instance name or a collection of a single instance object as returned by the get_instance command.

- **-new_leaf_name** ***leaf_inst_name***

  A required switch and value pair that specifies the new leaf name to assign to the instance object referenced in obj_spec.

- -silent

  An optional argument that specifies to ignore any of the two following error conditions: the instance within obj_spec does not exist or if an object already exists with the same leaf_inst_name within the parent_instance.

Example 1

The following example renames the leaf name and3 to my_and3.

```
rename_instance /modB/and3 -new_leaf_name my_and3
```

Example 2

The following example identifies all instances having the user-defined attribute is_my_type set to true and adds a special prefix called “myPrefix_” to their leaf instance name such that it will be easier to find them in the downstream steps of the flow using the SDC command “get_cells myPrefix_* -hierarchical”.

```
foreach_in_collection inst [ get_instance -filter “is_my_type”] {
        set leaf_name [get_attribute_value_list $inst -name leaf_name]
        rename_instance $inst -new_leaf_name myPrefix_${leaf_name}
}
```

replace_instances

Context: all contexts

Mode: insertion

Usage

replace_instances ***obj_spec1*** **-with_module** ***obj_spec2*** [-silent]

Description

Replaces the module definition of an instance with a new module definition.

The module definition assigned to the instance during instantiation is replaced with the module specified by the module within obj_spec2.

Connections to pins that exist on both the original and new module remain unchanged. New pins that did not exist on the original module are left open after the replacement. Pins that existed on the original module but do not exist on the new module are silently disconnected.

This command returns a collection containing the new instance.

If obj_spec1 does not exist, the tool generates an error. You can use the -silent switch to specify to not generate an error message when the object within obj_spec1 does not exist. If obj_spec2 is the same module as the original module, no change is made.

Arguments

- ***obj_spec1***

  A required value that is an instance name, a Tcl list of instance names, or a collection of instances as generated by the get_instances command.

- **-with_module** ***obj_spec2***

  A required switch and value pair that specifies the new module object to assign to the instances within obj_spec1. The obj_spec2 value must be a single module name or a collection of a single module object as created by the s command.

- -silent

  An optional argument that specifies to ignore specified objects of obj_spec1 or obj_spec2 that do not exist and to not generate error messages.

Example 1

The following example replaces the module definition of the instance u1/u2 with the module named nor2.

```
replace_instances u1/u2 -with_module nor2
```

Example 2

The following example replaces the module definition for instance u1/u2 to ModB. The original connection to pin u1/u2/a is preserved while the new pin u1/u2/b is left open.

get_attribute_value_list u1/u2 -name module_name

```
{ModA}
```

get_fanin u1/u2/a -stop_on net

```
{u1/n45}
```

replace_instances u1/u2 -with_module ModB

```
{u1/u2}
```

get_fanin u1/u2/a -stop_on net

```
{u1/n45}
```

get_fanin u1/u2/b -stop_on net

```
{}
```

report_aborted_faults

Context: dft -edt, patterns -scan

Mode: analysis

Usage

report_aborted_faults [*format_type*] [{> | >>} *file_pathname*]

Description

Displays information on testable faults that remain undetected (UD) after the ATPG process.

The report_aborted_faults command can help you determine why the tool aborted faults in the undetected fault list. You can then analyze whether to change the current abort limit to possibly allow ATPG to generate tests for those faults before the tool aborts them. To change the abort limit, use the set_abort_limit command.

Arguments

- *format_type*

  An optional literal that specifies the type of information that you want the tool to display regarding the aborted faults. The literal choices for the *format_type* argument are as follows:

  Summary — A literal that displays a summary of the number of aborted faults for each category. This is the default.

  All — A literal that displays all the aborted faults that are currently in the undetected fault list.

  Backtrack — A literal that displays all the aborted, undetected faults that exceeded the backtrack limit.

  CLock_restriction — A literal that displays all the aborted, undetected faults that had multiple clocks turned on.

  DECisions — A literal that displays all the aborted, undetected faults that exceeded the maximum number of decisions.

  DETected — A literal that displays all the faults that the tool aborted and then later detected.

  Edt — **(Available only when EDT is on)** A literal that displays EDT aborted faults. When the tool generates an effective fault test but is unable to compress the pattern, the fault is classified as an EDT aborted fault. Each of the following increases the probability of EDT aborted faults:

  - Relatively aggressive compression (large chain-to-channel ratio)
  - Large number of ATPG constraints
  - Relatively small design

  INterrupt — A literal that displays all the undetected faults that the tool aborted because you interrupted the ATPG process with a Control-C.

IDdq_restriction — A literal that displays all the undetected faults that the tool aborted while trying to satisfy the IDDQ restrictions.

Ram_sequential — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between the ram_sequential patterns.

SPace — A literal that displays all the aborted, undetected faults that required more memory space than was allocated.

TIme — A literal that displays all the undetected faults that the tool aborted because of the CPU time limitations.

TRansition — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between the initial and final transition pattern.

Write_pass_thru — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between write off and write on for RAM pass through patterns.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example

The following example displays the default summary of all the aborted faults:

report_aborted_faults

```
10 backtrack
1  clock_restriction
2  time
```

report_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_atpg_constraints[[{> | >>} *file_pathname*] [-Display {DEBug}]]

Description

Displays all the current ATPG state restrictions and the pins on which they reside.

The report_atpg_constraints command displays the pins and their state restrictions defined using the add_atpg_constraints command. The tool uses the state restrictions (constraints) during the ATPG process.

Arguments

- > *file_pathname*

  An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

- -Display DEBug

  An optional switch and literal that specify to display the specific ATPG state of the primary input(s) as callouts in the Debug window.

Example

The following example creates two ATPG pin constraints and then displays the information on those definitions:

add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
report_atpg_constraints

```
0 /I$135/Q (23)
1 and_b_in
```

Related Commands

add_atpg_constraints

delete_atpg_constraints

report_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_atpg_functions [{> | >>} *file_pathname*]

Description

Displays all the current ATPG function definitions.

The report_atpg_functions command displays the definitions of the ATPG functions created using the add_atpg_functions command. You can use an ATPG function as an argument to the add_atpg_constraints command, which then lets you create state restrictions on pins that the tool uses during the ATPG process.

Arguments

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example

The following example creates two ATPG functions and then displays their definitions:

add_atpg_functions and_b_in and /i$143/q /i$141/q /i$142/q
add_atpg_functions select_b_in select /i$144/q /i$142/q
report_atpg_functions

```
USER_AND and_b_in
  Input 0:  /I$143/Q (27)
  Input 1:  /I$141/Q (23)
  Input 2:  /I$142/Q (25)
SELECT   selet_b_in
  Input 0:  /I$144/Q (29)
  Input 1:  /I$142/Q (25)
```

report_atpg_timing

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_atpg_timing [{> | >>} *file_pathname*]

Description

Reports the current ATPG timing setup.

For complete information, see "Using Timing-Aware ATPG" in the *Tessent Scan and ATPG User's Manual*.

The report uses the following format:

```
//  ATPG timing                        = { ON | OFF }
//  Timing source                      = { no timing |
                                           SDF minimum delay |
                                           SDF typical delay |
                                           SDF maximum delay }
//  Hold PIs                           = { ON | OFF }
//  Mask POs                           = { ON | OFF }
//  Exclude inter-clock paths          = { ON | OFF ]
//  Timing scale                       = { N/A | 1 ms | 1 us |
                                           1 ns | 1 ps }
//  Slack margin for fault dropping    = { OFf | slack_margin |
                                           slack_margin_percentage% }
//  Delay fault distribution function = { UNIFORM | HIstogram
                                        | EXPONENTIAL | INV_POLY }
//        [ f(t)=function(t), (begin time = min and end time = max ) ]

//  Longest delay (rising, falling)    = ( max_rising, max_falling )
//  Clock waveform                     = { UNDEFINED | USER DEFINED}//
//    Clock Name          Test Clock             System Clock
//                {Period, Offset, Width}   {Period, Offset, Width}
//    ---------------------------------------------------------------
//    clock_name     num1,num2,num3            num1,num2,num3
...
```

- **ATPG timing** — The status of timing-aware ATPG.
- **Timing source** — The source of the timing information.
- **Hold PIs** — The state of holding PIs when doing static timing analysis for arrival time, propagation time, path delay, and slack.
- **Mask POs** — The state of masking POs when doing static timing analysis for arrival time, propagation time, path delay, and slack.
- **Exclude inter-clock paths** — The state of excluding inter-clock paths when doing static timing analysis for arrival time, propagation time, path delay, and slack.

- **Timing scale** — The time units used. The timing scale is set by the SDF file and defaults to 1 ns.
- **Slack margin for fault dropping** — The margin specified using the set_atpg_timing command.
- **Longest delay** — From static timing analysis.
- **Clock waveform** — The clock information specified by the set_atpg_timing command and reports the following:
  - **Clock Name**
  - **Test Clock** — The ATE testing clock frequency, which may not be the same as the normal operation frequency (System Clock). Timing-aware ATPG uses the test clock frequency.
  - **System Clock** — Normal operating frequency.

Arguments

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example shows the timing-aware ATPG settings.

```
read_sdf top_worst.sdf
set_atpg_timing -clock test_clk_dd 16000 8000 8000
set_atpg_timing -clock test_clk_cc 8000 4000 4000
set_atpg_timing -clock test_clk_aa 4000 2000 2000
set_atpg_timing -clock default 36000 18000 18000
set_atpg_timing on
report_atpg_timing
```

```
//  ATPG timing                          = ON
//  Timing source                        = SDF typical delay
//  Time scale                           = 1 ns
//  Slack margin for fault dropping      = OFF
//  Delay fault distribution function    = EXPONENTIAL
// f(t) = 0.00158*e^(-0.0021t) + 4.94e-06, (begin time=0, end time=50000)

//  Longest delay (rising, falling)      = (50547.0000, 50547.0000)

//  Clock waveform                       = USER DEFINED
//
//    Clock Name                Test Clock                System Clock
//                        {Period, Offset, Width}   {Period, Offset, Width}
//    ---------------------------------------------------------------------
```

```
//    /test_clk_dd (4)     16000, 8000, 8000        16000, 8000, 8000
//    /test_clk_cc (3)      8000, 4000, 4000         8000, 4000, 4000
//    /test_clk_aa (2)      4000, 2000, 2000         4000, 2000, 2000
//    /clk_in (6)          36000, 18000, 18000      36000, 18000, 18000
```

set_atpg_timing

report_attributes

Context: unspecified, all contexts

Mode: all modes

Usage

Usage 1: Creates a report of attributes defined on a list of objects

report_attributes ***obj_spec*** [-predefined | -user_defined] [-silent] [-verbose]

Usage 2: Creates a report of attributes defined for specific object types

report_attributes **-object_types *type_list*** [-predefined | -user_defined] [-silent] [-verbose]

Usage 3: Creates a report for a specific attribute name

report_attributes **-name *attribute_name*** [-silent] [-verbose]

Usage 4: Creates a report of all registered attributes

report_attributes [-predefined | -user_defined] [-silent] [-verbose]

Description

Creates a human readable report for the set of attributes based on the usage options.

In all usages, specifying the -predefined option restricts the report to only predefined attributes and specifying the -user_defined option restricts the report to only user-defined attributes.

Usage 1: Creates a tabular report for the attributes set on any object found in ***obj_spec.*** The attributes on an object that are inherited from an associated object are reported. For example, an attribute registered for the module object type and set on a given module object is reported in the list of attributes for the instances of that module. By default, attributes which have not been set on the objects are not listed in the report unless the attribute was registered with the -show_default option.

If an object in ***obj_spec*** does not exist, an error message is displayed unless the -silent switch is specified.

Usage 2: Creates a tabular report for all attributes registered on the specified object types. These do not include the inherited attributes from one object type to another such as the module attributed inherited by the associated instances.

Usage3: Creates a tabular detailed report for a specific attribute.

Usage 2: Creates a tabular report for all registered attributes

Arguments

- ***obj_spec***

  A required value used in Usage 1 that specifies an object name, a Tcl list of object names or a collection of objects.

- **-object_types *type_list***

  A required value used in Usage 2 to enumerate the object types for which the attribute report is requested. The currently supported object types are module, port, instance, pin and net. The list of supported object types will be augmented in successive releases and eventually all object types with be available for reporting.

- -name *attribute_name*

  An optional switch and string pair that specify the name of the attribute whose information is to be reported. This argument is mutually exclusive with the obj_spec and -object_types type_list arguments.

- -predefined | -user_defined

  An optional switch that constrains the report to only pre-defined attribute names or only user-defined attribute names. If this argument is not specified, by default no constraints are applied and both pre-defined and user-defined attributes are reported

- -silent

  An optional switch that specifies to suppress error messages if there are objects in the ***obj_spec*** that do not exist.

- -verbose

  An optional switch that specifies to report the full list of possible attribute values. By default, only one line is dedicated to reporting the attribute values; additional values are truncated and replaced with "...".

Example 1

The following example reports the attribute definitions using the report_attributes command:

report_attributes

```
Attribute Definition Report

Attributes defined for all objects:

Name     Object   Type     Class          Default  Constraints
-----------------------------------------------------------------------
name     all      string   Pre-defined    -        -
speed    pin      integer  User-defined   200      100 to 500
added_by net      string   User-defined   John     John Patrick Susan
```

The same result would be achieved by executing:

report_attributes -object_types all

Example 2

The following example reports the attribute definitions for the pin object type:

report_attributes -object_types pin

```
Attribute Definition Report

Attributes defined for 'pin' objects:

Name     Object   Type     Class          Default  Constraints
-----------------------------------------------------------------
name     all      string   Pre-defined    -        -
speed    pin      integer  User-defined   200      100 to 500
```

Example 3

The following example reports the attribute definitions only for a list of pin objects:

report_attributes {u7/CLK u6/A2}

```
Attribute Definition Report

Attributes defined for object 'u7/CLK':
Name                   Value   Inheritance
---------------------  ------  -----------
base_name              u7      -
direction              input   -
is_valid               true    -
leaf_name              CLK     -
module_name            dff     -
name                   u7/CLK  -
object_type            pin     -
parent_instance                -
parent_is_hard_module  true    -

Attributes defined for object 'u6/A2':
Name                   Value  Inheritance
---------------------  -----  -----------
base_name              u6     -
direction              input  -
is_valid               true   -
leaf_name              A2     -
module_name            xor3   -
name                   u6/A2  -
object_type            pin    -
parent_instance               -
parent_is_hard_module  true   -
```

Example 4

The following example reports the attribute definitions for the speed attribute:

report_attributes -name speed

```
Attribute Definition Report

Name: Speed
Description:

    This attribute is used to hold the target frequency that the pin is
    allowed to have.
    The allowed frequency range of 100 to 500 was chosen to match
    the technology spec.

Global Option Settings:
Setting              Value
---------------------------------------------
Class                User-Defined
Type                 int
Default              200
Show_Default         false
Minimum              100
Maximum              500
Object               pin

Specific 'pin' Type settings:
Name                                 Value
---------------------------------------------
dense                                false
export_to_netlist                    off
save_in_flat_model                   off
preserve_boundary_in_flat_model      off
```

Example 5

The following example reports the possible cell_type attribute values with the -verbose switch both enabled and disabled.

report_attribute -name cell_type

```
Attribute Definition Report

Name:
        cell_type

Description:
This is a library model attribute

Setting       Value
------------  -------------------------------------
Class         Pre-Defined
Value_Type    string
Enum          and buffer clock_and clock_buffer ...

GUI_Strings   cell_type = %
Object_Types  module

report_bist_capture_ranges

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_bist_capture_ranges

Description

Displays a list of the currently defined BIST capture ranges.

The report_bist_capture_ranges command displays a list of the capture ranges that are currently defined as a result of the add_bist_capture_range command. A BIST capture range is defined by a named capture procedure that is stored in the test procedure file, and a range of patterns that will use this capture procedure. The complete range of patterns reported by the report_bist_capture_ranges command typically represents a small subset of the entire pseudo-random pattern space, and is applied to the complete pattern space by repeating the sequence until all the pseudo-random patterns have been simulated.

Example

The following example shows the output from the report_bist_capture_ranges command.

report_bist_capture_ranges

```
// List of currently dedined Logic BIST capture ranges
// Procedure name  from pattern  to pattern
// --------------  ------------  ----------
// cap1                0           14
// cap2               15           15
//
// NOTE: This list defines the active named capture range during pseudo-
// random pattern simulation. The tool automatically restarts at the top
// of the list when the pattern counter matches the final "to pattern"
// value.
```

Related Commands

add_bist_capture_range

delete_bist_capture_ranges

report_black_boxes

Context: all contexts

Mode: all modes

Usage

report_black_boxes {{**-Instances** [*ins_pathnames*]} | {**-Modules** [*module_names*]} | **-All** | **-Undefined**} [{> | >>} *file_pathname*]

Description

Displays information on blackboxes and undefined models.

The report_black_boxes command reports on the status of any instance- or module-based blackboxes, or undefined models that are not yet blackboxed. The report follows the following format.

```
MODULE: module_name (default tie value = 0|1|X|Z)
  SYSTEM: Inout|Output pin pin_name tied to 0|1|X|Z
  USER: Inout|Output pin pin_name tied to 0|1|X|Z
INSTANCE: ins_name (default tie value = 0|1|X|Z)
  SYSTEM: Inout|Output pin pin_name tied to 0|1|X|Z
  USER: Inout|Output pin pin_name tied to 0|1|X|Z
```

For module-based blackboxes, the tool displays the string MODULE followed by the name of the module and the default tie value (0, 1, X, or Z). The tool then displays a list of module pins. For each pin, the tool displays either SYSTEM or USER followed by the direction type of the pin (Inout or Output), the name of the pin, and its tied value. SYSTEM declares that the pin is tied to the default value by the system while USER declares that you explicitly tied the pin to the specified value.

For instance-based blackboxes, the report replaces the string MODULE with INSTANCE to explicitly declare that it is an instance-based blackbox.

Arguments

- **-Instances** [*ins_pathnames*]

  A switch and optional string that specify for the tool to display information on instance-based blackboxes. The ins_pathnames argument can be an instance, a Tcl list of instances, or a collection of instances. If you do not specifiy an ins_pathname, the tool displays information on all instance-based blackboxes. If you specify an instance pathname, it reports on that single, instance-based blackbox.

- **-Modules** [*module_names*]

  A switch and optional string that specify for the tool to display information on module-based blackboxes. The module_names argument can be an instance of the Verilog module or ATPG library model, a Tcl list of instances, or a collection of instances. If you do not supply a module_name, the tool displays information on all module-based blackboxes. If you specify a *module_name*, it reports on that single, module-based blackbox.

- **-All**

  A switch that specifies for the tool to display information on all defined blackboxes, as well as undefined models. This is the command default.

- **-Undefined**

  A switch that specifies for the tool to display information on undefined models that have not yet been blackboxed. Use this switch to determine whether your design is complete, or is missing library models. If you intend to blackbox undefined models, this report allows you to verify that only the intended models are undefined.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of file_pathname.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of file_pathname.

Example

The following example defines module- and instance- based blackboxes then reports on them.

add_black_boxes -module core -pin do1 0 -pin io1 1
add_black_boxes -instance core1 1 -pin do0 0 -pin io0 0
report_black_boxes -all

```
Default tie value = X
MODULE: core
SYSTEM: Output pin do0 tied to X
  USER: Output pin do1 tied to 0
  SYSTEM: Inout pin io0 tied to X
  USER: Inout pin io1 tied to 1
INSTANCE: core1
  USER: Output pin do0 tied to 0
  SYSTEM: Output pin do1 tied to 1
  USER: Inout pin io0 tied to 0
  SYSTEM: Inout pin io1 tied to 1
```

report_bus_data

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_bus_data ***type*** [{> | >>} *file_pathname*]

Description

Displays the bus data information for either an individual bus gate or for the buses of a specific type.

The report_bus_data command displays the following bus information:

- Instance name
- Gate identification number
- Contention handling (pass, bidi, fail, or abort)
- Type of bus (strong or weak)
- Number of drivers on the bus
- Any learned behavior of the bus.

The design rule that checks for bus contention mutual exclusivity is rule E10. For more information on rule E10, refer to the "Extra Rules (E Rules)" section.

If you enable the learn reporting by using the set_learn_report command, the tool provides the following two additional lines of information with the report_bus_data command:

- Information on whether or not the bus is capable of being set to an X, set to a Z, or having multiple drivers turned on.
- A list of drivers and their corresponding gate type. Drivers that are equivalent have a gate type of EQ.

The design rule that checks to see if there is any possible input combination that can force a bus into the high-impedance state (Z) is rule E11. For more information on rule E11, refer to the "Extra Rules (E Rules)" section.

Arguments

- ***type***

  A required literal or integer that specifies the type of bus for which you want the tool to display information. The choices for the *type* argument are as follows:

  gate_id# — An integer that specifies the gate identification number whose bus data you want to display.

  ALl — A literal that displays the bus data for all buses.

Weak — A literal that displays the bus data for the weak buses.

Strong — A literal that displays the bus data for the strong buses.

Dominant — A literal that displays the bus data for the final bus of every set of cascaded buses.

NONDominant — A literal that displays the bus data for all but the final bus in every set of cascaded buses.

Pass — A literal that displays the bus data for the buses that passed the contention mutual exclusivity checking.

Bidi — A literal that displays the bus data for the bidirectional buses that have possible contention problems. For the tool to place a bus in this category, the bidirectional pin must have only a single tri-state driver.

Fail — A literal that displays the bus data for the buses that failed the contention mutual exclusivity checking.

ABort — A literal that displays the bus data for the buses that aborted contention mutual exclusivity checking.

Buf — A literal that displays the bus data for all buses that have the buffer learned behavior.

Xor — A literal that displays the bus data for all buses that have the exclusive OR learned behavior.

Mux — A literal that displays the bus data for all buses that have the multiplexer learned behavior.

AND — A literal that displays the bus data for all buses that have the AND learned behavior.

OR — A literal that displays the bus data for all buses that have the OR learned behavior.

POSS_Mult_dr_on — A literal that displays the bus data for all buses that have a possibility of having multiple drivers turned on at the same time.

POSS_X — A literal that displays the bus data for all buses that have a possibility of being at an unknown state.

POSS_Z — A literal that displays the bus data for all buses that have a possibility of being at the high-impedance state.

HIstogram — A literal that displays a summary of information identifying the number of buses that are in each of the possible categories.

ZPass — A literal that displays the bus data for the buses that pass the E11 design rule.

ZFail — A literal that displays the bus data for the buses that fail the E11 design rule check.

ZAbort — A literal that displays the bus data for the buses that abort the E11 design rule check.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

The following example displays the information on a specific bus gate—an inverter (INV):

report_bus_data 31

```
/FA1/XOR1/OUT/ (31)Handling=pass type=strong #Drivers=2 (INV)
   Bus Drivers:  30(SW) 28(SW)
```

Example 2

The following example first enables access to the static learning data, then displays both the learned information and the bus data on a specific bus gate, again, an inverter (INV):

set_learn_report on
report_bus_data 31

```
/FA1/XOR1/OUT/ (31)Handling=pass type=strong #Drivers=2 (INV)
   Learn Data :  poss_X=no, poss_Z=no, poss_mult_drivers_on=no
   Bus Drivers:  30(SW) 28(SW)
```

Related Commands

set_learn_report

report_bypass_chains

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_bypass_chains
[-All_blocks | {-Edt_chain *chain_name*} | {-Bypass_chain *chain_number*}]
[{> | >>} *file_pathname*]

Description

Displays the defined EDT bypass scan chain connections.

If issued from Setup mode, the report_bypass_chains command lists scan chain connections for bypass scan chains defined using the set_bypass_chains command.

If issued from analysis mode, all bypass scan chain connections are reported, whether defined by Tessent TestKompress or with the set_bypass_chains command.

You can display the chain connection information for all bypass chains, or optionally include the -Edt_chain or -Bypass_chain switch to display only the information for a particular bypass chain. The order, left to right, in which the display lists the scan chains in a particular bypass chain is the order in which the chains are series-connected from channel input to channel output.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the chain connection information as described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays information for all the EDT bypass chains in every EDT block. You set the current EDT block using either the add_edt_blocks or set_current_edt_block command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “Modular Compressed ATPG” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

This switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tessent TestKompress flow, you do not need this switch.

An optional switch that specifies to display all chain connection information for all EDT blocks. Without this switch, the tool displays information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- **-**Edt_chain *chain_name*

  An optional switch and string pair that specify to display the scan chain connections for only the EDT bypass chain that includes the EDT scan chain, *chain_name*. You can use this switch to see which bypass chain or scan channel is associated with a particular scan chain.

- **-**Bypass_chain *chain_number*

  An optional switch and positive integer pair that specify to display the scan chain connections for the EDT bypass chain, *chain_number*. Use this switch to list the scan chain connections for a particular EDT bypass chain. The *chain_number* is the same as the number of the scan channel connected to the bypass chain.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

Assume a design has eight scan chains named “chain1” through “chain8” and that the chains have been incorporated into two EDT bypass channels configured from two EDT scan channels. The following example displays the scan chain connection information for the EDT bypass chain containing chain3. You can see from the report that chain3 is part of a bypass chain connected to scan channel 2.

report_bypass_chains -edt_chain chain3

```
//    Reporting user-defined bypass chains:
//
//    Bypass#  EDT chains
//    -------  ------
//       2     chain2, chain3, chain4, chain7, chain8
```

Example 2

The following example displays the connection information for EDT bypass chain 1 (scan channel 1).

report_bypass_chains -bypass_chain 1

```
//    Reporting user-defined bypass chains:
//
//    Bypass#  EDT chains
//    -------  ------
//       1     chain1, chain5, chain6
```

Again, notice that the EDT bypass chain number (Bypass# in the display) is the same as the number of the scan channel to which the bypass chain is connected.

Related Commands

reset_bypass_chains

set_bypass_chains

report_capture_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_capture_handling [List | SUmmary | SOurces | SInks | Gates]
[{> | >>} *file_pathname*]

Description

Displays any special data capture handling currently in use.

To change how the tool handles data capturing on level-sensitive and trailing-edge state elements, use the add_capture_handling command. If you have not set up any special data capture handling, then the report_capture_handling command does not generate a report.

Arguments

- List

  A literal that displays the handling settings (old, new, or X), whether the element is a sink or source, the instance pathname, and the gate identification number. This is the default.

- SUmmary

  A literal that displays the handling settings for both level-sensitive and trailing-edge state elements, the number of sources, the number of primitive gates in the flattened netlist between source and sink points, and the number of sinks.

- SOurces

  A literal that displays the gates that have source-point, special data capture handling.

- SInks

  A literal that displays the gates that have sink-point, special data capture handling.

- Gates

  A literal that displays the identification numbers of all the primitive gates between the source and sink points.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example

The following example sets up the data capture handling for one gate, and then issues the set_capture_handling command to identify the associated sinks for that source:

add_capture_handling new 1158 -source
set_capture_handling

The following set of commands show the different formats for the available reports:

report_capture_handling

```
NEW Source /I_1_16/DF0/ (1158)
```

report_capture_handling list

```
NEW Source /I_1_16/DF0/ (1158)
```

report_capture_handling summary

```
Capture handling summary: LS=OLD, TE=NEW, #sources=1,
                                          #int_gates=14, #sinks=2
```

report_capture_handling source

```
Source list : 1158-X
```

report_capture_handling sink

```
Sink list : 1160-X 1165-X
```

report_capture_handling gates

```
Int_gate list: 13 14 39 40 51 52 53 61 62 63 68 69 79 86
```

Related Commands

add_capture_handling

set_capture_handling

report_capture_procedures

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_capture_procedures [-CLock_sequence]
[-CReated_capture_procedure | -Loaded_capture_procedure | -ENabled | -Disabled | *capture_procedure_name*...] [-All | -Summary | -Internal | -External] [-Display Wave] [{> | >>} *file_pathname*]

Description

Displays the cyclized information for a specified named capture procedure.

Cyclizing is a processing step performed prior to ATPG that merges internal mode cycles when needed to optimize them and/or expand other internal mode cycles to ensure correct simulation results.

For example, when a named capture procedure contains a cycle that pulses multiple clocks at different times, the cycle must be expanded into multiple cycles (one for each clock pulse) in order to simulate it. The cyclized information shows the cycles ATPG will actually use when creating patterns, after any merging or expansion of cycles. The display also includes comments about the timing of the cycles and where the at-speed sequences begin and end to aid your understanding.

The displayed information resembles the original procedure as defined in the test procedure file, but it does not have any timeplates. Therefore, it will not work if copied and pasted as is into a dofile; you must add timeplates. To display the procedure as it actually exists in the test procedure file, use the report_procedures command.

The number of cycles reported is the sequential depth used during test generation. The display of merged or expanded cycles is illustrated in the examples. See also "Displaying Named Capture Procedures" in the *Tessent Scan and ATPG User's Manual*.

Note

If the named capture procedure is modified to cyclize it for ATPG, the modifications are internal only; the named capture procedure is not altered in the test procedure file.

Arguments

- -Clock_sequence

  An optional switch that displays the clock sequence of the named capture procedures. The scan load cycle(s), at-speed cycle(s), and the number of patterns the named capture procedure is associated with are also displayed.

- -Created_capture_procedure

  An optional switch that displays only the created named capture procedures.

- -Loaded_capture_procedure

  An optional switch that displays only the named capture procedures loaded from the read_procfile command or from the procedure file associated with the scan group definition.

- -Enabled

  An optional switch that displays only enabled named capture procedures.

- -Disabled

  An optional switch that displays only disabled named capture procedures.

- *capture_procedure_name*

  An optional, repeatable string that displays only the specified named capture procedures. By default, information for all named capture procedures is displayed.

- -All

  An optional switch that displays information for both the internal and external modes of the named capture procedure. This is the default.

- -Summary

  An optional switch that displays only summary information about the named capture procedure.

- -Internal

  An optional switch that displays information for only the internal mode of the named capture procedure.

- -External

  An optional switch that displays information for only the external mode of the named capture procedure.

- -Display Wave

  An optional switch that displays the specified capture procedure in the Wave window of DFTVisualizer. This is for optimized NCP's. Use the report_procedures command to display unoptimized NCP's.

- > *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list to create or replace the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list to append the contents of *file_pathname*.

Example 1

The following example displays summary information for the named capture procedures *nam_cap1*, *nam_cap2*, *my_cap1*, and *my_cap2*, including the scan load cycle(s), the at-speed cycle(s), and the number of patterns with which the named capture procedures are associated. It

also indicates *nam_cap1* and *nam_cap2* were loaded from an external file and *my_cap1* and *my_cap2* were internally created.

report_capture_procedures -summary

```
capture_proc_name  cycles  at_speed_cycle  active  source   # associated patterns
                                                             internal  external
-----------------  ------  --------------  ------  -------  ---------  ---------
nam_cap1             1          1          no     loaded        0         -
nam_cap2             1          1          yes    loaded       10         -
my_cap1              2        {1 to 2}     yes    created       5         -
my_cap2              2        {2 to 2}     no     created       0         -
```

Example 2

The following example displays the clock sequence of the named capture procedures *capture1*, *capture2*, *user_capture_proc*, and *user_capture_proc_1* in addition to the summary information.

report_capture_procedures -clock_sequence

```
capture_proc_name  cycles  at_speed_cycle  active  source   # associated patterns  capture_clock_sequence
                                                             internal   external
-----------------  ------  --------------  ------  -------  ----------  ----------  ----------------------
capture1             1          1          yes    loaded        6           -      S(c4,c3,c2,c1,c0)
capture2             1          1          yes    loaded        8           -      S(c9,c8,c7,c6,c5)
user_capture_proc    3       {1 to 3}      yes    created       0           -      S(c0)(c1,c0)(c3,c2)
user_capture_proc_1  3       {1 to 3}      yes    created       0           -      S(c0),(c1,c0)(c3,c2)
```

Example 3

The following example displays information for all the named capture procedures (*capture1*, *capture2*, and *my_cap1*). The first line displayed for each named capture procedure indicates if the procedure is currently enabled for test generation (ACTIVE) or disabled (INACTIVE). You can enable or disable capture procedures with the set_capture_procedures command.

report_capture_procedures

```
procedure capture "capture1" = //  (INACTIVE) (loaded capture procedure)
    cycle = // cycle 1 starts at time 0 (Begin_AC_test) (Force PI) (Measure
PO)
      condition  "/inst_0/clkenhold/reg_sco/"  1 ;
      force  "/clock[4]"  0 ;
      force  "/clock[3]"  0 ;
      force  "/clock[2]"  0 ;
      force  "/clock[1]"  0 ;
      force  "/clock[0]"  0 ;
      force  "/clear"  0 ;
      force  "/scan_en"  0 ;
      force  "/test_clk"  0 ;
      force_pi ;
      measure_po ;
      pulse "/clock[1]" ;
      pulse "/clock[0]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "capture1"

procedure capture "capture2" = //  (ACTIVE) (loaded capture procedure)
```

```
   cycle = // cycle 1 starts at time 0 (Begin_AC_test) (Force PI) (Measure
PO)
      condition  "/inst_0/clkenhold/reg_sco/"  0 ;
      force  "/clock[4]"  0 ;
      force  "/clock[3]"  0 ;
      force  "/clock[2]"  0 ;
      force  "/clock[1]"  0 ;
      force  "/clock[0]"  0 ;
      force  "/clear"  0 ;
      force  "/scan_en"  0 ;
      force  "/test_clk"  0 ;
      force_pi ;
      measure_po ;
      pulse "/clock[4]" ;
      pulse "/clock[3]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "capture2"

procedure capture "my_cap1" = //  (ACTIVE) (created capture procedure)
    cycle = slow // cycle 1 starts at time 0 (Force PI)
      force  "/clock[4]"  0 ;
      force  "/clock[3]"  0 ;
      force  "/clock[2]"  0 ;
      force  "/clock[1]"  0 ;
      force  "/clock[0]"  0 ;
      force  "/clear"  0 ;
      force  "/scan_en"  0 ;
      force  "/test_clk"  0 ;
      force_pi ;
      measure_po ;
      pulse "/clock[4]" ;
      pulse "/clock[3]" ;
    end ; // cycle 1
    cycle = // cycle 2 starts at time 50 (Begin_AC_test) (Force PI)
(Measure PO)
      condition  "/inst_0/clkenhold/reg_sco/"  0 ;
      force  "/clock[4]"  0 ;
      force  "/clock[3]"  0 ;
      force  "/clock[2]"  0 ;
      force  "/clock[1]"  0 ;
      force  "/clock[0]"  0 ;
      force  "/clear"  0 ;
      force  "/scan_en"  0 ;
      force  "/test_clk"  0 ;
      force_pi ;
      measure_po ;
      pulse "/clock[2]" ;
      pulse "/clock[1]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "my_cap1"
```

Example 4

The following example displays how the tool will use the cycle during ATPG (the command's output is excerpted for brevity):

report_capture_procedures -internal

```
...
   Mode internal =
      Cycle =   // cycle 1 starts at time 0 (Begin_AC_test)
                // (Force PI)
         Force_pi ;
         Pulse /clk1 ;
      End ;    // cycle 1 at time 20
      Cycle =  // cycle 2 starts at time 20
         Pulse /clk2 ;
      End ;    // cycle 2 at time 50
...
```

The display shows that for this particular design and cycle definition, the tool expands the one cycle from the test procedure file into two cycles internally. Notice that the combined time of the two cycles is the same as the period of the original cycle in the test procedure file. The tool will automatically adjust the sequential depth used during ATPG to accord with the resultant change in number of cycles.

Example 5

The next example shows a case where the tool merges two cycles described in the test procedure file into one cycle for ATPG. The relevant excerpts from the test procedure file are shown first; the example then displays the cyclized data for the three cycles.

```
mode_internal =
...
   timeplate tp2;
   cycle =
      force_pi;
      force tms 0;
      pulse clk;
   end;
   cycle =
      force tms 0;
   end;
   cycle =
      force tms 0;
      pulse clk;
   end;
...
```

```
timeplate tp2 =
   force_pi 0;
   pulse clk 10 10;
   period 50;
end;
```

report_capture_procedures -internal

```
...
   Mode internal =
      Cycle =  // cycle 1 starts at time 0 (Begin_AC_test)
         // (Force PI)
         Force_pi ;
         Force /tms 0 ;
```

```
   Pulse /clk ;
End ;    // cycle 1 at time 100
Cycle =  // cycle 2 starts at time 100
   Force /tms 0 ;
   Pulse /clk ;
End ;    // cycle 2 at time 150
```

report_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_cell_constraints [-Scan_cell | -Non_scan_cell]
[{-CHain *chain_name*} | {-CLock *clock_name*}]
[{> | >>} *file_pathname*]

Description

Displays a list of the constrained cells.

The report_cell_constraints command displays a list of all the scan cells (also non-scan cells for DX and SX constraints) that you previously constrained to a constant value using the add_cell_constraints command. The display may consist of up to seven columns, as follows (columns that contain no data for all cell constraints are not displayed):

- Constraint value — Specifies the constraint value.
- Chain name — Specifies the scan chain name if the constraint is on a scan cell. If the constraint is on a non-scan cell, then this column is blank.
- Cell position — Specifies the position in the scan chain if the constraint is on a scan cell. If the constraint is on a non-scan cell, then this column is blank.
- Cell instance name — Specifies the cell instance of the constraint. This column is blank unless you originally specified the constraint with a *pin_pathname*.
- Gate instance name — Specifies the gate instance of the constraint. This column is blank unless you originally placed the constraint on a non-scan cell using the -Clock switch.
- Constraint properties — Displays constraint properties, as applicable, from the following list:.
  - Internal — Constraint was applied by the tool automatically in response to certain DRC results
  - Whole Chain — Constraint was applied using the -Chain switch
  - Drc C6 — Constraint was applied using the “-Drc C6” argument combination.
  - Clock — Constraint was applied using the -Chain switch
  - Drc D8 Warn — Constraint was applied by the tool automatically to a D8 failing master cell when “set_drc_handling d8 warning” was in effect for DRC. See “D8” for more information.
  - Dynamic — Constraint was applied in Analysis mode
  - Static — Constraint was applied in Setup mode

- Pattern scope — Specifies the pattern scope of the constraint: whether the tool uses the constraint only when creating scan patterns, or uses the constraint for both scan and chain pattern creation.

Arguments

- -Scan_cell

  An optional switch that specifies to report_cell_constraints at scan cells only. This switch is valid in Analysis mode only.

- -Non_scan_cell

  An optional switch that specifies to report_cell_constraints at non-scan cells only. This switch is valid in Analysis mode only.

- -CHain *chain_name*

  An optional switch and string pair that specifies to report_cell_constraints added to the scan chain, *chain name*, by an earlier add_cell_constraints -Chain command. This switch is valid in Analysis mode only.

- -CLock *clock_name*

  An optional switch and string pair that specifies to report the cell constraints added by an earlier add_cell_constraints -Clock command to latches and flip-flops controlled by the clock, *clock_name*. This switch is valid in Analysis mode only.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

The following example begins in Setup mode and constrains a single scan cell to be at a constant zero for the generation of all patterns. The example then displays current cell constraints, leaves Setup mode, triggering the tool's automatic DRC process and again reports the cell constraints:

add_cell_constraints sdff1/q c0 -all_patterns
report_cell_constraints

```
// constraint cell_instance  constraint     pattern scope
//    value       name       properties
// ---------- -------------  ---------- ---------------------
//     C0        sdff1/q      (Static)  Chain + Scan Patterns
```

set_system_mode analysis
report_cell_constraints

```
// const chain  cell    cell_inst constraint     pattern scope
```

```
// value  name  pos        name   properties
// ----- -----  -----  ---------- ---------- ---------------------
//   C0    c1    2        sdff1/q  (Static)  Chain + Scan Patterns
```

Notice that once the tool has identified the scan chains during the DRC process, the report identifies the chain and cell position of the constrained scan cell.

Example 2

The next example adds DX constraints on all flip-flops clocked by clk2. You can see from the cell constraint report that these flip-flops are not scan cells (no chain or cell position). Notice also that the gate instances are reported for them since each flip-flop is a standalone gate, not part of a scan cell.

add_cell_constraints -clock /clk2 -type flop dx
report_cell_constraints

```
// const chain  cell  cell_inst gate_inst constraint     pattern scope
// value  name  pos      name     name    properties
// ----- ----- ------ --------- --------- ---------- --------------------
//   DX                          /dff6   (Clock)    Scan Patterns only
//                                       (Dynamic)
//   DX                          /dff5   (Clock)    Scan Patterns only
//                                       (Dynamic)
//   C0    c1    2      sdff1/q          (Static)   Chain + Scan Pattern
```

Related Commands

add_cell_constraints

delete_cell_constraints

report_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Usage

report_cell_models [-All | {-Type *cell_model_type*}]

Description

Displays a list of either all cell models or the DFT library models associated with the specified cell type.

The report_cell_models command displays the cell models that you either added with the add_cell_models command, or described in the DFT library with the cell_type attribute.

Arguments

- -All

  An optional switch that specifies to display all cell model definitions that you added with the add_cell_models command. This is the default.

- -Type *cell_model_type*

  An optional switch and literal pair that specifies to display a listing of all the cell models of a particular type. The valid cell_model_types are as follows (with the minimum typing characters shown in uppercase):

  INV — A literal that specifies a one-input inverter gate.

  And — A literal that specifies a two-input AND gate.

  Buf — A literal that specifies a one-input buffer gate.

  OR — A literal that specifies a two-input OR gate.

  NAnd — A literal that specifies a two-input NAND gate.

  NOr — A literal that specifies a two-input NOR gate.

  Xor — A literal that specifies a two-input exclusive OR gate.

  Mux — A literal that specifies a 2-1 multiplexer.

  Scancell — A literal that specifies a cell with four input pins (clock, data, scan in, and scan enable), clocked scan cell with four inputs (clock, data, scan clock, and scan enable), or LSSD scan cell with five inputs (clock, data, scan in, master clock, and slave clock).

  DFf — A literal that specifies a D flip-flop with two input pins (clock and data).

  LATCH — A literal that specifies a D latch with two input pins (enable and data).

Examples

The following example displays a list of all added cell models:

```
add_clocks 0 clk
set_test_logic -set on -re on -clock on
set_system_mode analysis
report_dft_check
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux s a b
add_cell_models nor2 -type nor

report_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_chain_masks

Description

Reports the list of masked scan chains and their associated unload value.

Arguments

None

Example

The following example adds several chain masks and then reports the added chain masks:

add_chain_masks chain2 chain4 chain5
report_chain_masks

```
// Masked scan chain Unload value Cell constraints
// ----------------- ------------ ----------------
//      chain2             X              OX
//      chain4             X              OX
//      chain5             X              OX
```

The following example adds several chain masks, specifies load values, and then reports the added chain masks:

add_chain_masks chain2 -load_value 0
add_chain_masks chain4 -load_value 0
add_chain_masks chain5 -load_value 1
report_chain_masks

```
// Masked scan chain Load value Unload value Cell constraints
// ----------------- ---------- ------------ ----------------
//      chain2           0            X              OX
//      chain4           0            X              OX
//      chain5           1            X              OX
```

Related Commands

delete_chain_masks

report_clock_controller_pins

Context: dft -logic_bist

Mode: setup, analysis

Usage

report_clock_controller_pins [> | >> *file_pathname*]

Description

Reports the clock controller pins specified with the set_clock_controller_pins command.

This command is used with the hybrid TK/LBIST flow—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example

This example reports all clock_controller pins specified so far using the set_clock_controller_pins command.

report_clock_controller_pins

```
//
//  PinType                  Connection
//  -------                  ----------
//  Shift clock              clock_control_i1/SLOW_CLK
clock_control_i2/SLOW_CLK clock_control_i3/SLOW_CLK
//  Scan enable              clock_control_i1/SCAN_EN
clock_control_i2/SCAN_EN clock_control_i3/SCAN_EN
//  LBIST enable            clock_control_i1/LBIST clock_control_i2/LBIST
clock_control_i3/LBIST
//  Capture procedure index  NCP_INDEX_1/A NCP_INDEX_0/A
//
```

Related Commands

set_clock_controller_pins

set_lbist_power_controller_options

report_clock_controls

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_clock_controls

Description

Displays current configuration information for clock control definitions.

For more information, see "Support for Internal Clock Control" in the *Tessent Scan and ATPG User's Manual*.

Example

The following example illustrates how clock control definitions are reported.

The following clock control is defined in a test procedure file.

```
clock_control clk =
   source_clock pll_clk;
   atpg_cycle 0=
     condition ctl_dff2/Q 1;
   end;
   atpg_cycle 1=
     condition ctl_dff1/Q 1;
   end;
end;
```

The Report Clock Control command reports the definition as follows:

report_clock_controls

```
CLOCK_CONTROL "/clk (6)" =
SOURCE_CLOCK "/pll_clk (4)";
   ATPG_CYCLE 0 =
   CONDITION "/ctl_dff2/ (56)" 1;
  END;
   ATPG_CYCLE 1 =
   CONDITION "/ctl_dff1/ (55)" 1;
  END;
END;
```

Related Commands

set_clock_controls

report_clock_domains

Context: dft -edt, patterns -scan

Mode: analysis

Usage

report_clock_domains [{-Compatible_clocks [-Details]} | {-Race_points *clk1 clk2*}] [{> | >>} *file_pathname*]

Description

Displays all clocks and their corresponding clock domain numbers.

During ATPG, if “set_clock_restriction domain_clock” is set, the tool may simultaneously turn on any subset of compatible clocks. This allows fault effects to be captured by more than one clock in the same cycle without risk of simulation mismatches due to clock skew. As a result, the test pattern count may be reduced and the fault coverage improved for the same clock sequential depth, compared with when only one clock is turned on in each cycle.

The report_clock_domains command lists defined clocks by groups based on their compatibility. Clocks are compatible (occupy the same clock domain) if capturing with them simultaneously can be performed reliably. Use this command to assess the overall clock compatibilities in your design, and to determine if using “set_clock_restriction domain_clock” would be beneficial.

Note

The basic display enables you to quickly evaluate the overall clock compatibility of your design. It is summary information, however, and does not necessarily show the compatibility relationship between all possible clock pairings. That is, two clocks listed with different clock domains are not necessarily incompatible. Use the -Compatible_clocks switch if you need to check the compatibility information for a specific pair of clocks.

Arguments

- -Compatible_clocks

  An optional switch that includes in the display the pair-wise clock compatibility information the tool uses during ATPG. Because two clocks with different clock domain numbers are not necessarily *in*compatible, this switch enables you to determine precisely whether two clocks are compatible or not.

  The tool treats two clocks as compatible if the clocks can be in their “on” state at the same time without causing clock skew problems or race conditions. To make this determination, the tool analyzes the clocking relationship between source and sink memory elements where the source is clocked by one clock and the sink is clocked by a different clock.

Table 7-22 summarizes the conditions under which the tool determines the two clocks to be compatible (C) or incompatible (I).

Table 7-22. Clock Compatibility Summary

Source	Sink			
	LE[1]	TE[2]	AH[3](TE)	AL[4](LE)
LE	I	C	C	I
TE	C	I	I	C
AH (LE)	I	C	C	I
AL (TE)	C	I	I	C

1. LE = Captures on PI clock's leading edge
2. TE = Captures on PI clock's trailing edge
3. AH = Active high, level sensitive element
4. AL = Active low, level sensitive element

- -Details

  An optional switch that displays the same compatibility information provided by the -Compatible_clocks switch, but instead of using an "x" in the display to mark each incompatible clock pair, use as the marker the number of state elements at which the tool determined the pair to be incompatible.

- -Race_points *clk1 clk2*

  An optional switch and pair of strings that lists the instances that cause the two clocks, *clk1* and *clk2*, to be incompatible. The tool includes the gate ID and type of state element (scan, non-scan or RAM) for each instance listed.

- > *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list or creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list for appending to the contents of *file_pathname*.

Example 1

The following example displays the defined clocks and their domains of the design. The numbers in parentheses are the unique gate identification numbers assigned to each gate during the model flattening process.

set_system_mode analysis
report_clock_domains

```
// Clock name   Domain
// -------------------
// /ck11m (8)        1
```

```
// /ck22m (9)         1
// /ck2_75m (10)      2
// /ck5_5m (11)       2
// /nreset (39)       3
// /scan_reset (63)   4
//
// 6 clocks classified into 4 domains.
// This is only one of the possible clock classifications. To see all
dependencies of clock pairs, use 'report_clock_domains -Compatible_clocks'
```

Example 2

The following example displays the clock domains in example 1 with added information about the possible clock pairs in the design. Notice that although the tool assigned the /scan_reset clock to a domain different from the others, it is actually incompatible only with clocks /ck2_75m, and /nreset. This is indicated by an "x" in the /scan_reset row, above the index number that corresponds to each of those two clocks.

report_clock_domains -compatible_clocks

```
// No:Clock name  Domain | Clock compatibility
// ----------------------+---------------------
// 1: /ck11m (8)        1| .
// 2: /ck22m (9)        1| ..
// 3: /ck2_75m (10)     2| .x.
// 4: /ck5_5m (11)      2| ....
// 5: /nreset (39)      3| .xxx.
// 6: /scan_reset (63)  4| ..x.x.
// ----------------------+---------------------
//                    No.| 123456
// . = Compatible clock pair
// x = Incompatible clock pair
//
// 6 clocks classified into 4 domains.
// This is one of possible clock classifications.
```

Example 3

The following example displays the same information as the preceding example, but directs the tool to substitute for each "x" the number of state elements at which the tool found the pair to be incompatible.

report_clock_domains -compatible_clocks -details

```
// No:Clock name  Domain | Clock compatibility
// ----------------------+---------------------
// 1: /ck11m (8)        1| .
// 2: /ck22m (9)        1| . .
// 3: /ck2_75m (10)     2| . 3 .
// 4: /ck5_5m (11)      2| . . . .
// 5: /nreset (39)      3| . 6 1 6 .
// 6: /scan_reset (63)  4| . . 8 . 4 .
// ----------------------+---------------------
//                    No.| 1 2 3 4 5 6
//        . = Compatible clock pair
// <number> = Incompatible clock pair
```

```
//
// 6 clocks classified into 4 domains.
// This is one of possible clock classifications.
```

The report shows there are three state elements that cause clocks /ck2_75m and /ck22m to be incompatible. The next example lists the instance name, gate ID and type of element for each of these elements.

report_clock_domains -race_points /ck2_75m /ck22m

```
//    /ff30/ (57) non-scan
//    /ff31/ (58) non-scan
//    /ff31b/ (58) non-scan
//  3 state elements cause clocks "/ck2_75m" and "/ck22m" to be
//  incompatible.
```

Example 4

The following example uses the add_norace_clocks command to define three clocks as compatible even though the analysis has determined two of the three possible pairings from among the three clocks are incompatible. The example then reports on the compatibility of clock pairs. In the resultant report, you can see that an “n” is used in place of the “.” if the add_norace_clocks command was applied to a clock pair that the tool already determined was compatible; and an “N” is used if the norace definition was applied to an incompatible pair.

add_norace_clocks /ck22m /ck5_5m /nreset
report_clock_domains -compatible_clocks

```
// No: Clock name  Domain | Clock compatibility
// -----------------------+--------------------
// 1: /ck11m (8)         1| .
// 2: /ck22m (9)         1| ..
// 3: /ck2_75m (10)      2| .x.
// 4: /ck5_5m (11)       2| .n..
// 5: /nreset (39)       3| .NxN.
// 6: /scan_reset (63)   4| ..x.x.
// -----------------------+--------------------
//                     No.| 123456
// . = Compatible clock pair
// x = Incompatible clock pair
// n = User-defined norace between compatible clk pair (1)
// N = User-defined norace between incompatible clk pair (2)
//
// 6 clocks classified into 4 domains.
// This is one of possible clock classifications.
//
// Warning: 2 incompatible clock pair(s) overwritten by the user as norace
clock pair(s).
```

Note

The tool assumes you have expert knowledge when you override its analysis, but will remind you of the override with a warning.

report_clock_gating

Context: dft -scan, dft -test_points

Mode: analysis

Usage

report_clock_gating [-LIbrary_model *library_model_name*…]
[-Module *module_object*...] [-INStance *instance_object*...]
[{> | >>} *file_pathname*]

Description

Reports the clock gating instances that were identified as having unconnected ports and were connected to either the scan enable signal or to a user-specified signal or, reports the unconnected ports of the specified clock gating cells only.

Arguments

- -LIbrary_model *library_model_name*

  An optional switch and a repeatable string that specify the library model name(s) of the clock gating cell instances to be reported for unconnected ports to be connected to either the scan enable signal or the specified signals.

- -Module *module_object*

  An optional switch and string pair that specify the netlist module name(s) of the clock gating cell instances to be reported for unconnected ports to be connected to the specified signals. The module_object can be a single module name, a TCL list of module names, or a collection of module objects as returned by the get_modules command.

- -INstance *instance_object*

  An optional switch and string pair that specify the hierarchical pathname(s) of the clock gating cell instances to be reported for unconnected ports to be connected to either the scan enable signal or the specified signals. The instance_object can be a single instance pathname, a TCL list of instance pathnames, or a collection of instance objects as returned by the get_instances command.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of file_pathname.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of file_pathname.

Examples

The following example connects the unconnected scan enable ports of specified clock gating instances. The first instance is connected to the sen1 pin, which drives the signal with the active state set to low. The next two instances are connected to the default scan enable signal, sen.

The results of these commands are shown by the report_clock_gating command output:

```
set_scan_enable sen
set_clock_gating -instance clkg1/clkg1/clkgLA -driver sen1 -active low
set_clock_gating -instance {clkg3/clkg1/clkgLA clkg2/clkg1/clkgLA}
set_system_mode analysis

// Note: The following clock gating instances have unconnected ports that
will be connected to a scan enable signal.

Related Topics

set_clock_gating

report_clocks

Context: all contexts

Mode: setup, analysis

Usage

report_clocks [-All | -User | -Sdc] [-Display {[DEBug] [DESign] [DAta] [Wave] | ALl} [APpend]] [{> | >>} *file_pathname*]

Description

Displays a list of all user-defined clocks and SDC-defined clocks.

The report_clocks command lists all user-defined clocks created with the add_clocks command or all SDC-defined clocks created by an SDC file loaded with the read_sdc command or both.

Arguments

- -All | -User | -Sdc

  A 1-of-3 choice of optional switches that report user-defined clocks or SDC clocks or both. User-defined clocks are created by the add_clocks command and SDC clocks are created by the SDC file loaded with the read_sdc command. -All is the default option when the flat model is available. Note that the -Sdc switch is valid only when the flat model is available.

  For information about the user-defined clocks report, refer to Example 3. For information about the SDC clocks report, refer to Example 4.

- -Display {[DEBug] [DESign] [DAta] [Wave] | ALl} [APpend]

  An optional switch and repeatable literal that specify to display the instance(s) in the specified window; if Append is specified, the instances are added to the existing contents of the window instead of replacing the contents. The window choices are as follows:

  DEBug
  Specifies the Debug window. This is the default.

  DESign
  Specifies the Design window.

  DAta
  Specifies the Data window.

  Wave
  Specifies the Wave window.

  ALl
  Specifies all supported windows.

- > *file_pathname*

  An optional redirection operator and pathname pair for creating *or* replacing the contents of file_pathname.

- *>> file_pathname*

  An optional redirection operator and pathname pair for appending to the contents of file_pathname.

Example 1

The following example adds two clocks to the clock list and then displays a list of the clocks:

add_clocks 1 clk1
add_clocks 0 clk0
report_clocks

```
User-defined Clocks (2):
 ---------  -----------  --------  -------  ----------------
 Off State  Constraints  Internal  Name     Other Properties
 ---------  -----------  --------  -------  ----------------
     1                      No     clk1
     0                      No     clk2
```

Example 2

The following example adds two clocks to the clock list and then displays a list of the clocks:

add_clocks 1 clk_0 clk_1 clk_2 clk_3 -internal -pin_name group_clk

```
// Note: Adding primary input group_clk merging 4 nets.
```

report_clocks

```
User-defined Clocks (1):
 ---------  -----------  --------  ---------   ---------------------  ------
 Off State  Constraints  Internal  Name        Other Properties       Pin(s)
 ---------  -----------  --------  ---------   ---------------------  ------
     1                     Yes    group_clk   (merged internal pin)  clk_0
                                                                      clk_1
                                                                      clk_2
                                                                      clk_3
```

Example 3

The following example reports only user-defined clocks:

> **report_clocks -user**

```
User-defined Clocks (4):
---------  --------------  ------------  --------  ------------- ----------------- ------------
Off State  Constraints     Type          Internal  Name          Other Properties  Pin(s)
---------  --------------  ------------  --------  ------------- ----------------- ------------
   0       Free Running                  Yes       /CG/occ/gclk                    /CG/occ/gclk
   0       Asynchronous                  No        /refclk       (period:1.67ns)
   1       Always Capture  shift-MASTER  No        /clk
   1       -               shift-MASTER  Yes       /Extclk0                        /CG/Extclk0
```

The following explains the columns in the report:

- Off State — Lists the off state of the clock as defined by the add_clocks command.
- Constraints — Lists the special constraint of the clock specified with the add_clocks command:
  - Free Running — The clock is defined with the -free_running switch.

  - Asynchronous — The clock is defined with the -free_running and -period switches.
  - Always Capture — The clock is defined with the -always_capture switch.
- Type — Lists the type of clocks learned by DRC. This is reported only when the tool is in a non-setup mode.
- Internal — Indicates whether the clock is defined on an internal pin (using the “add_clocks -internal” command).
- Name — Lists the name of the clock.
- Other Properties — Lists any additional properties of the clock.
- Pin(s) — Lists one or more internal pins that are connected to the clock.

Example 4

The following example reports only SDC clocks:

> **report_clocks -sdc**

```
SDC-defined Clocks (3):
------------  ---------- ------------ ---------  ------ ----------------------------------
Type          Add_clocks Create_clock Divide_by   Name    Nodes
------------  ---------- ------------ ---------  ------ ----------------------------------
Source             X            X                clk1x  /clk1 (1)
  Generated                                 2     clk2x  /CG/occicg_clk2x_top_inst/gclk (26)
  Generated                                 4     clk4x  /CG/occicg_clk4x_top_inst/gclk (36)
```

The report groups the generated clocks under the source clock from which they’re derived. The following explains the columns in the report:

- Type— Lists the type of SDC clock, which is either a Source clock (from SDC create_clock command) or a Generated clock (from the SDC command create_generated_clock).
- Add_clocks — Indicates if the clock is also defined with the add_clocks command.
- Create_clock — Indicates when a source clock is defined using SDC create_clock command.
- Divide_by — Lists the divide_by ratio of the clock (from the SDC command “create_generated_clock -divide_by”).
- Name — Lists the name of the clock.
- Nodes — Lists the target nodes of the clock.

Example 6

The following example adds two internal clocks and then shows the output of the report clocks report_clocks command.

SETUP> **add_clocks 0 -pin_name clock_1x_int -internal clk1_inst/Y clk2_inst/Y clk3_inst/Y**
SETUP> **add_clocks 0 -pin_name clock_2x_int -internal clk4_inst/Y clk5_inst/Y clk6_inst/Y**
SETUP> **report_clocks**

```
User-defined Clocks (2):
 ---------  -----------  --------  ------------  ---------------------  ------
 Off State  Constraints  Internal  Name          Other Properties       Pin(s)
 ---------  -----------  --------  ------------  ---------------------  ------
    0                   Yes       clock_2x_int (merged internal pin) clk4_inst/Y
                                                                     clk5_inst/Y
                                                                     clk6_inst/Y
    0                   Yes       clock_1x_int (merged internal pin) clk1_inst/Y
                                                                     clk2_inst/Y
                                                                     clk3_inst/Y
```

report_compactor_connections

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Usage

report_compactor_connections [-All_blocks | {-CHANnel *channel_number*} | {-CHAIn *chain_name*}] [{> | >>} *file_pathname*]

Description

Displays defined scan chain connections for each EDT scan channel output.

If issued from Setup mode, the report_compactor_connections command lists scan chain connections for EDT scan channel outputs previously defined using the set_compactor_connections command.

If issued from analysis mode, all compactor connections are reported, whether defined by Tessent TestKompress or with the set_compactor_connections command.

You can display the chain connection information for all scan channel outputs, or optionally include the -Channel or -Chain switch to display the information only for a particular scan chain or channel.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the chain connection information as described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays information for all the EDT scan channel outputs in every EDT block. You set the current EDT block using either the add_edt_blocks or set_current_edt_block command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “Modular Compressed ATPG” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

This switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tessent TestKompress flow, you do not need this switch.

An optional switch that specifies to display all chain connection information for all EDT blocks. Without this switch, the tool displays the information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- **-**CHANnel *channel_number*

  An optional switch and positive integer pair that specify to display the scan chain connections for only the scan channel identified by *channel_number*.

- **-**CHAIn *chain_name*

  An optional switch and string pair that specify to display the scan chain connections for only the scan channel whose compactor group includes *chain_name*. Use this switch to see which scan channel is associated with a particular chain.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Example 1

Assume a design has eight scan chains named “chain1” through “chain8”, whose outputs currently have user-specified connections through the compactor to two EDT scan channels. These user-defined connections are the result of previous set_compactor_connections commands.

The following example displays the compactor connection information for the chain3 scan chain. You can see from the report that chain3 is part of a compactor group that also includes chain4 and chain5; also that the outputs of these three chains are currently specified to be compacted into the output of scan channel number 2.

report_compactor_connections -chain chain3

```
//    Reporting user-defined compactor connections:
//
//    Channel     Chains
//    -------     ------
//       2        chain3 - chain5
//
```

Example 2

The following example looks up the connection information for scan channel number 1.

report_compactor_connections -channel 1

```
//    Reporting user-defined compactor connections:
//
//    Channel     Chains
//    -------     ------
//       1        chain1, chain2, chain6, chain7, chain8
//
```

report_config_data

Context: all contexts including unspecified

Mode: all modes

Usage

report_config_data [config_object [-in_wrapper *wrapper_object_or_name*]
[-partition *partition_name*]}] [-show_unspecified]
[-levels integer | all] [-indent *integer*]

Description

Reports the content of configuration wrappers in the transcript as it appears inside the file when the configuration data is written to file using the write_config_data command.

Like all report commands, you can use the > command to redirect the output into a file.

Arguments

- ***config_spec***

  A required value that specifies the name of a configuration element or a collection containing one configuration element. When config_spec is a collection, the -in_wrapper and -partition options cannot be used because the object contains all of the information about the configuration element. In order to use the -in_wrapper option, the config_spec value must be a name and the name must be relative to the specified wrapper element. You can use a positional id for any level of hierarchy. You can also replace the id of a leaf name by the position. For example, the path “tmp(1)/<0>/wrp<1>” means “tmp(1)/wrp(abc)/wrp(def)” if “wrp(abc)” is the first element found inside “tmp(1)” and “wrp(def)” is the second instance of a wrapper with a base name of “wrp” inside “tmp(1)/wrp(abc)”.

- -in_wrapper *wrapper_object_spec*

  An optional option value pair that is used to specify the parent wrapper in which the configuration element exists. The wrapper_object_spec value is the name of a wrapper or a collection containing a wrapper element. The names in the config_element_name_list are relative to the specified parent wrapper.

- -partition *partition_name*

  An optional option value pair that is used to specify the parent wrapper in which the configuration element exists. When the option is unspecified, the default partition is used which is where all specifications (DftSpecification and DefaultsSpecification/DftSpecification) are located. You can access the Core wrappers comprising the Tessent Core Description syntax in the tcd partition. Using the partition

names meta: and meta:tcd allows you to access the metadata configuration elements that define the default and tcd partitions. Table 7-23 summarizes the available partition names.

Table 7-23. Available Partition for Introspection

Partition name	Configuration data contained
	When the -partition option is unspecified, the Default partition is access which is where the DftSpecification and DefaultsSpecification/DftSpecification configuration data is located.
tcd	When the -partition option is specified with the tcd value, the Core wrappers comprising the Tessent Core Description syntax is accessed
meta	When the -partition option is specified with the meta value, the metadata configuration data defining the allowed syntax of the DftSpecification and DefaultsSpecification/DftSpecification is accessed.
meta:tcd	When the -partition option is specified with the meta:tcd value, the metadata configuration data defining the allowed syntax of the Core wrappers is accessed.

Example 1

The following example creates some configuration elements and then reports them. The last command uses the > myfile to output the reported data into a file called *myfile*.

```
> add_config_element tmp(1)
{/tmp(1)}
> add_config_element tmp(1)/p1 -value v1 -type property
{/tmp(1)/p1}
> add_config_element tmp(1)/p2 -value v2 -type property
{/tmp(1)/p2}
> add_config_element tmp(1)/w1 -type wrapper
{/tmp(1)/w1}
> add_config_element tmp(1)/w1/P1 -value v1 -type property
{/tmp(1)/w1/P1}
> add_config_element tmp(1)/w1/P2 -value v2 -type property
{/tmp(1)/w1/P2}
> add_config_element tmp(1)/w2 -copy_from tmp(1)/w1
{/tmp(1)/w2}
> report_config_data

tmp(1) {
  p1 : v1;
  p2 : v2;
  w1 {
    P1 : v1;
    P2 : v2;
  }
  w2 {
    P1 : v1;
    P2 : v2;
```

```
    }
  }
  > report_config_data tmp(1) -level 1

  tmp(1) {
    p1 : v1;
    p2 : v2;
    w1 {
      // Not shown
    }
    w2 {
      // Not shown
    }
  }
  > report_config_data tmp(1) -level 1 > myfile
```

Example 2

This example shows how config data is reported when it is of type CSV. The read_config_data is used to parse a CSV file generated from Excel. Notice how the format of the data is changed when only reporting the content of the CSV wrapper as opposed to the CSV Wrapper itself. The same feature exists in the write_config_data command such that you can export CSV data back to Excel.

```
> add_config_element csv(1)
CDV(1)
> read_config_data mydata.csv -in csv(1)
> report_config_data
csv(1) {
  "", "", "", "", "";
  a, b, c;
  "a,c", d;
  "", "", "";
}
> report_config_data csv(1)

,,,,
a,b,c
"a,c",d
,,
```

report_config_messages

Context: all contexts

Mode: all modes

Usage

report_config_message **config_spec**
[-hierarchical]
[-all | [-error] [-warning] [-info]]

Description

Reports messages associated to a configuration element. When the -hierarchical option is used, it also reports the messages associated to elements below the specified wrapper.

Arguments

- *config_object_spec*

  A required value that specifies the name of a configuration element or a collection containing one configuration element.

- -hierarchical

  An optional switch that can only be used when the config_object_spec is a wrapper and specifies that the command should also return elements below the specified wrapper having at least one config message of the specified types.

- -all

  An optional Boolean option that specifies that all message types are to be returned. The use of the -all option is mutually exclusive to the specification of the -error, -warning and -info options. When none of the four options is specified, -all is assumed.

- -error

  An optional Boolean option that specifies that the messages to be returned are of type error. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

- -warning

  An optional Boolean option that specifies that the messages to be returned are of type warning. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

- -info

  An optional Boolean option that specifies that the messages to be returned are of type info. The use of the -error option is mutually exclusive to the specification of the -all, -warning,

and -info options. When none of the -error, -warning and -info options is specified, -all is assumed.

Example

The following example adds configuration messages of type error, warning and info on some elements and reports them.

```
> add_config_element tmp(1)
{/tmp(1)}
> add_config_element tmp(1)/p1 -value v1 -type property
{/tmp(1)/p1}
> add_config_element tmp(1)/p2 -value v2 -type property
{/tmp(1)/p2}
> add_config_element tmp(1)/w1 -type wrapper
{/tmp(1)/w1}
> add_config_element tmp(1)/w1/P1 -value v1 -type property
{/tmp(1)/w1/P1}
> add_config_element tmp(1)/w1/P2 -value v2 -type property
{/tmp(1)/w1/P2}
> add_config_element tmp(1)/w2 -copy_from tmp(1)/w1
{/tmp(1)/w2}
> add_config_message "Message1" -config_object tmp(1)/w1 -error
{/tmp(1)/w1}
> add_config_message "Message2" -config_object tmp(1)/w1/P2 -info
{/tmp(1)/w1/P2}
> add_config_message "Message3" -config_object tmp(1)/w1/P2 -warning
{/tmp(1)/w1/P2}
> report_conf_message tmp(1)/w1

Report for errors, warnings, infos
  /tmp(1)/w1
    E0) Message1

> report_conf_message tmp(1)/w1 -hierarchical

Report for errors, warnings, infos
  /tmp(1)/w1
    E0) Message1
  /tmp(1)/w1/P2
    W0) Message3
    I0) Message2
```

Related Commands

add_config_message

get_config_messages

report_config_syntax

Context: all contexts

Mode: all modes

Usage

report_config_syntax *config_or_meta_object_spec*
[-properties_only | -wrappers_only]
[-levels *integer*]

Description

Reports the available configuration syntax found below the specified config_or_meta_object_spec element.

If you refer to the meta path, you only need to specify the wrapper and property names such as DftSpecification/IjtagNetwork even though the real path name is Wrapper(DftSpecification)/Wrapper(IjtagNetwork). If you have a configuration element such as DftSpecification(corea,rtl)/IjtagNetwork, you can use it too and it will look up the metadata of the element and report its syntax.

Three optional options limit the amount of syntax displayed to only wrapper, only properties, or to a specified sub-level count.

Arguments

- *config_or_meta_object_spec*

  A required string that specifies the configuration wrapper for which you want to see the available syntax. If you refer to the meta path, you only need to specify the wrapper and property names such as “DftSpecification/IjtagNetwork” even though the real meta path name is “Wrapper(DftSpecification)/Wrapper(IjtagNetwork)”. If you have a configuration element such as DftSpecification(corea,rtl)/IjtagNetwork, you can use it too and it will look up the metadata of the element and report its syntax.

- -properties_only

  An optional Boolean option that restricts the command to only show the properties at the top level of the specified wrapper.

- -wrappers_only

  An optional Boolean option that restricts the command to only show the wrappers and exclude the properties.

- -level *integer*

  An optional option value pair that specifies the number of sub-wrappers to show. When unspecified, all sub-levels are shown.

Example

The following example uses the report_command to show the available syntax currently avalable in the DftSpecification wrapper limiting the levels to 2.

The second example shows the entire syntax available in the Tdr wrapper.

```
> set_context dft -rtl
> report_config_syntax DftSpecification -level 2
DftSpecification(<module_name>,<id>) {
  rtl_extension               : <string>  ; // default: v
  gate_extension              : <string>  ; // default: vg
  reuse_modules_when_possible : <boolean> ; // default: auto
  IjtagNetwork {
    DataInPorts {
    }
    DataOutPorts {
    }
    HostScanInterface(<id>) {
    }
  }
}
> report_config_syntax \
      DftSpecification/IjtagNetwork/HostScanInterface/Tdr
DftSpecification(<module_name>,<id>) {
  IjtagNetwork {
    HostScanInterface(<id>) {
      Tdr(<id>) {
        Interface {
          tck            : <port_name>       ; // default: ijtag_tck
          reset          : <port_name>       ; // default: ijtag_reset
          select         : <port_name>       ; // default: ijtag_sel
          shift_en       : <port_name>       ; // default: ijtag_se
          capture_en     : <port_name>       ; // default: ijtag_ce
          update_en      : <port_name>       ; // default: ijtag_ue
          scan_in        : <port_name>       ; // default: ijtag_si
          scan_out       : <port_name>       ; // default: ijtag_so

          reset_polarity : <active_polarity> ; // legal : active_high
(active_low)
        }
        DataInPorts {
          count       : <int>            ; // default: auto
          port_naming : <port_name>, ... ; // default: ijtag_data_in[%d]
          connection(<range>) : <pin_name> ; // repeatable
        }
        DataOutPorts {
          count        : <int>            ; // default: auto
         port_naming  : <port_name>, ... ; // default: ijtag_data_out[%d]
          multiplexing : <boolean>        ; // default: auto
          output_timing(<range>) : <timing_spec> ; // repeatable
          connection(<range>) : <pin_name> ; // repeatable
        }
        parent_instance              : <instance_name>      ;
        leaf_instance_name           : <leaf_instance_name> ;
       keep_active_during_scan_test : <boolean>        ; // default: auto
       length                      : <int>              ; // default: auto
       extra_bits_capture_value     : <enum>       ; // legal : 1 (0) self
```

```
            reset_value                  : <binary>     ; // default: auto
            Attributes {
              <attribute> : <string> ; // repeatable
            }
            DecodedSignal(<signal_name>) {
              decode_values : <binary_code>, ... ;
              multiplexing  : <boolean>          ; // default: auto
             output_timing : <timing_spec>; // legal : (auto) unlatched normal
    ijtag_scan_selection
              connection : <port_pin_name> ; // repeatable
              Attributes {
                <attribute> : <string> ; // repeatable
              }
            }
          }
        }
      }
    }
```

Related Commands

report_config_data

report_context

Context: unspecified, all contexts

Mode: all modes

Usage

report_context

Description

Reports the current context as specified by the set_context command and any inferred subcontexts.

This command also provides information about inferred sub-contexts as shown in the examples below.

Arguments

- None

Return Value

None

Example 1

In the following example, the command reports that it ran in uncompressed ATPG mode.

report_context

```
//  Context: patterns -scan -no_rtl
//  Uncompressed ATPG (no EDT) mode active.
```

Example 2

In the following example, the command reports that it is in extraction mode.

report_context

```
// Context: patterns -ijtag -no_rtl
// ICL extraction mode active.
```

Example 3

In the following example, the command reports that it is in compressed ATPG mode.

report_context

```
//  Context: patterns -scan -no_rtl
//  Compressed ATPG (EDT) mode active.
```

Example 4

In the following example, the command reports that it is in Logic BIST mode.

report_context

```
//  Context: patterns -scan -no_rtl
//  Logic BIST mode active.
```

Related Commands

get_context

set_context

report_control_signals

Context: dft -scan

Mode: analysis

Usage

report_control_signals {[-All] | {[*pin_pathname*…] [-Clock] [-Set] [-Reset] [-Write] [-Read] [-Tristate_enable]} [-Verbose] [-NOSTABLE_High] [-NOSTABLE_Low]

Description

Displays the rules checking results for control signals consisting of clocks added with the add_clocks command and pins identified for gating scannable memory elements with test logic.

Arguments

- -All

  An optional switch that outputs all control signals to the report. Default setting.

- *pin_pathname*

  An optional, repeatable string that specifies the pathnames of control signals to report on.

- -Clock

  An optional switch that outputs clock control signals in the report.

- -Set

  An optional switch that reports on all set control signals.

- -Reset

  An optional switch that reports on all reset control signals.

- -Write

  An optional switch that reports on all write control signals.

- -Read

  An optional switch that reports on all read control signals.

- -Tristate_enable

  An optional switch that reports on all tristate enable signals.

- -Verbose

  An optional switch that includes all memory elements associated with each control signal in the report.

- -NOSTABLE_High

  An optional switch that disables the report on any stable-high memory elements.

- -NOSTABLE_Low

  An optional switch that disables the report on any stable-low memory elements.

report_core_descriptions

Context: all contexts

Mode: all modes

Usage

report_core_descriptions

Description

Reports all core description files.

The tool uses the information in this file to retarget patterns for instances of the associated core.

Arguments

None.

Example

The following example shows the output of the report_core_descriptions command in two modes:

In setup mode:

```
report_core_descriptions

Name           Mode Name     Mode Type
------------   -----------   -----------
* chip         retargeting   retargeting

Note: * denotes current design
```

In analysis mode:

```
report_core_descriptions

Name               Mode        Mode        Instantiations  Chain     Scan
                   Name        Type                        Patterns  Patterns
----------------- ----------- ----------- --------------  --------  --------
* chip             retargeting retargeting
  piccpu_maxlen16 internal    internal    1               8         117

Note: * denotes current design
```

report_core_instances

Context: patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Mode: setup, analysis

Usage

report_core_instances [**-cores *core_names*** | -modules *module_objects* |
-instances *instance_objects*] [-silent]

Description

Reports the instance bindings created with the add_core_instances command, as well as the pattern count for patterns read in for each core.

If this command is invoked in analysis mode, the pattern count for each core is also reported.

You can specify the absolute instance path names or the module or core names. You can either report all core instances that have been added (the default), or filter by modules, instances, or core names.

Arguments

- **-cores *core_names***

  A switch and Tcl list that specifies the core names of the core descriptions from which all instance bindings should be reported.

- -modules *module_objects*

  An optional switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. This command reports the instance bindings for each instantiation of those modules in the design.

- -instances *instance_objects*

  An optional switch and string pair that specifies an object name, a Tcl list of object names (hierarchical names), or a collection of objects. This command reports the instance bindings for each instance in the list.

- -silent

  An optional switch that specifies to suppress warning messages.

Example 1

The following example reports all existing core instances while in setup mode.

report_core_instances

```
Instance  Core       Mode Name   Mode Type   Module
--------  ---------  ---------   ---------   -----------
core_1    my_core_1  internal    internal    my_module_1
core_2    my_core_2  internal    internal    my_module_2
core_3    my_core_3  internal    internal    my_module_3
```

Example 2

The following example reports all existing core instances while in analysis mode.

report_core_instances

```
Instance Core       Mode Name  Mode Type  Module      Chain      Scan
                                                      Patterns   Patterns
-------- ---------  ---------  ---------- ----------- --------   --------
core_1   my_core_1  internal   internal   my_module_1 12         10
core_2   my_core_2  internal   internal   my_module_2 12         10
core_3   my_core_3  internal   internal   my_module_3 6          74
```

Example 3

The following example first reports all core instances for modules my_module_1 and my_module_2 while in setup mode; it then reports the same while in analysis mode.

report_core_instances -modules {my_module_1 my_module_2}

```
Instance Core       Mode Name  Mode Type  Module
-------- ---------  ---------  ---------- -------------
core_1   my_core_1  internal   internal   my_module_1
core_2   my_core_2  internal   internal   my_module_2
```

set_system_mode analysis
...
report_core_instances -modules {my_module_1 my_module_2}

```
Instance Core       Mode Name  Mode Type  Module      Chain      Scan
                                                      Patterns   Patterns
-------- ---------  ---------  ---------  ----------- --------   --------
core_1   my_core_1  internal   internal   my_module_1 12         10
core_2   my_core_2  internal   internal   my_module_2 12         10
```

Example 4

The following example first reports core instances core_1 and core_3 while in setup mode; it then reports the same while in analysis mode.

report_core_instances -instances {core_1 core_3}

```
Instance Core       Mode Name  Mode Type   Module
-------- ---------- ---------  ---------- -----------
core_1   my_core_1  internal   internal   my_module_1
-------- ---------- ---------  ---------- -----------
core_3   my_core_3  internal   internal   my_module_3
```

set_system_mode analysis
...
report_core_instances -instances {core_1 core_3}

```
Instance Core      Mode Name  Mode Type  Module       Chain      Scan

report_design_sources

Context: all contexts

Mode: all modes

Usage

report_design_sources

Description

Reports the pathnames or file extensions previously specified with the set_design_sources command.

Arguments

None

Return Value

None

Example

The following example shows a report generated by this command:

set_design_sources -format icl -y ../data/icl_primitives -extension icl

set_design_sources -y ../data/verilog_primitives -extension v

report_design_sources

```
//  ICL search_design_load_path: activated
//  ---------------------------------------------------------------
//  format   type  path                          file extensions
//  -------  ----  ----------------------------  ---------------
//  Verilog  dir   '../data/verilog_primitives'  'v v.gz'
//  ICL      dir   '../data/icl_primitives'      'icl icl.gz'
```

Related Commands

report_dfm_rules

Context: patterns -scan_diagnosis

Mode: analysis

Usage

report_dfm_rules [-header | -col *columns*...]

Description

Returns a tabular report of the DFM rules contained in the layout database.

By default, all columns are listed. These are: id, rule, layer, and type.

For more information about DFM rules, see "Diagnosis for Design for Manufacturability Analysis."

Arguments

- -header

  An optional switch that returns a list of available column names.

- -col *columns*...

  An optional switch that specifies the column names you want to use for the DFM rule information in the report.

Example1

The following example creates a report that contains all available columns.

report_dfm_rules

```
-----------------------------------------------------------
  id   rule                                layer     type
-----------------------------------------------------------
  1    minimum_space_4_line_route1         route_1   BRIDGE
  2    metal_cross_edge_route1             route_1   OPEN
  3    low_density_min_space_route2        route_2   BRIDGE
  4    half_comb_route3                    route_2   OPEN
  5    metal_cross_edge_route1             route_3   OPEN
  6    corner_to_interior_metal4           route_4   BRIDGE
  7    divergent_line_with_jog_metal5      route_5   BRIDGE
  8    metal_cross_edge_route1             route_5   OPEN
  9    route_5_barbell                     route_5   OPEN
  10   route_2_between_vias                route_2   OPEN
-----------------------------------------------------------
```

Example 2

The following example creates a report that contains the rule name and the type.

report_dfm_rules -col rule type

```
-------------------------------------------
  rule                                type
-------------------------------------------
  minimum_space_4_line_route1       BRIDGE
  metal_cross_edge_route1           OPEN
  low_density_min_space_route2      BRIDGE
  half_comb_route3                  OPEN
  metal_cross_edge_route1           OPEN
  corner_to_interior_metal4         BRIDGE
  divergent_line_with_jog_metal5    BRIDGE
  metal_cross_edge_route1           OPEN
  route_5_barbell                   OPEN
  route_2_between_vias              OPEN
-------------------------------------------
```

Related Commands

get_dfm_rules

report_dft_check

Context: dft -scan

Mode: analysis

Usage

report_dft_check [-All | *instance_pathname*] [-FUll | -Scannable | -Nonscannable | {-Defined {Scan | Nonscan} | -Identified | -Unidentified | {-RUle {S1 | S2 | S3 | S4}} | -Tristate | -RAm] [{> | >>} *file_pathname*]

Description

Generates scannability check information for all non-scan instances in the design, or within a specific hierarchical instance.

The displayed or written report includes six columns of information as described here:

- The first column displays whether the DFT Rules Checker identified the non-scan instance as scannable or non-scannable.
- The second column displays whether the non-scan instance is unidentified, identified by the scan identification process, or defined as non-scannable or scannable with the add_nonscan_instances and add_scan_instances commands, respectively.
- The third column displays the clock that is associated with the non-scan instance, or displays “Test-Logic” to specify that test logic will be added to make the instance scannable. If the non-scan instance is identified as non-scannable, the third column displays the design rule ID number, where the non-scan instance failed the clock rules. The gate index number of the non-scannable instance is also shown, as well as the set, reset or clock primary inputs to the memory element that failed the rules checking.
- The fourth column displays the instance name of the non-scan instance.
- The fifth column displays the library model name associated with the instance.
- The sixth column displays “Stable-high” if the clock inputs of the non-scan instances are at a one-state, with respect to the clock primary inputs.

An example of the output of this command, along with additional information, is covered in “Reporting Scannability Information” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- -All

  An optional switch that specifies to display all non-scan instances for the entire design. This is the default.

- *instance_pathname*

  An optional string that specifies to report scannability information for the specified instance. If the instance pathname specifies a hierarchical instance, the tool generates scannability

information for all instances within that hierarchical block. If the instance pathname specifies a particular sequential instance, the tool generates scannability information for only that instance.

- -Full

  An optional switch that specifies to display the scannability check information for all non-scan instances. This is the default.

- -Scannable

  An optional switch that specifies to display the non-scan instances that the tool has identified during the rules checking process to be scannable.

- -Nonscannable

  An optional switch that specifies to display the non-scan instances that the tool has identified during the rules checking process to be non-scannable.

- -Defined Scan | Nonscan

  An optional switch and literal pair that specifies whether to display user-defined scan or non-scan instances. The valid literals are as follows:

  Scan — A literal that specifies to display scan instances defined with the add_scan_instances command.

  Nonscan — A literal that specifies to display non-scan instances defined with the add_nonscan_instances command.

- -Identified

  An optional switch that displays identified non-scan instances.

- -Unidentified

  An optional switch that displays unidentified non-scan instances.

- -RUle S1 | S2 | S3 | S4

  An optional switch and literal that specifies which non-scannable cell violations to report. For more information on S1, S2, S3, and S4 rule violations, refer to "Scannability Rules (S Rules)."

- -Tristate

  An optional switch that displays the enable lines of tri-state gates connected to the outputs of memory elements.

- -RAm

  An optional switch that displays the RAM gates identified to be controllable through test logic insertion.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list that for creates *or* replaces the contents of file_pathname.

- *>> file_pathname*

  An optional redirection operator and pathname pair used at the end of the argument list to append to the contents of file_pathname.

Examples

The following example displays the scannability check for all non-scan instances in the design:

add_clocks 1 clk1
add_clocks 0 clk0
set_system_mode analysis
report_dft_check

```
SCANNABLE     DEFINED-NONSCAN  /CLK1 /U1   FD1
SCANNABLE     IDENTIFIED       /CLK1 /U2   FD1
SCANNABLE     UNIDENTIFIED     /CLK1 /U3   FD1
SCANNABLE     DEFINED-SCAN     /CLK1 /U4   FD1
SCANNABLE     UNIDENTIFIED     /CLK2 /U5   FD1
SCANNABLE     IDENTIFIED       /CLK2 /U6   FD1
NON-SCANNABLE UNIDENTIFIED      S1   /U7   FD2 (34)
   Clock #1:   /CLK3 (11)
Number of non-scannable instances fails on S1 rule = 1
Number of instances found = 1
Number of instances reported = 1
```

Related Commands

echo
report_drc_rules
report_seq_transparent_procedures

report_diagnosis

Context: patterns -scan_diagnosis

Mode: analysis

Usage

report_diagnosis [-ENCoded] [-SHORT]

Description

Writes the scan diagnosis report to standard I/O.

Arguments

- -ENCoded

  An optional switch encoding the suspect's pin pathname, net name, and cell name in the diagnosis report.

- -SHORT

  An optional switch that suppresses the display of layout-aware diagnosis information in the diagnosis report.

Related Commands

write_diagnosis

report_display_instances

Context: all contexts

Mode: setup, analysis

Usage

report_display_instances {***gate_id#*** | ***instance_name***}… | **-All**
[-Display {DEBug | DESign | DAta}] [-Full]

Description

Shows netlist information for the specified instances displayed in the Debug, Design, or Data window.

The report_display_instances command reports, in the session transcript, netlist information for the specified instances currently displayed in the DFTVisualizer Debug, Design, or Data window. The default report includes the information listed in the following table:

Table 7-24. Default Netlist Information Reported for Instances

"set_gate_level Design" in effect	**"set_gate_level Primitive" in effect**
Instance name	Instance name
DFT library model name	Gate identification number
	Gate type

You can display the same information from a tool's command line using the report_gates command, whether or not DFTVisualizer is open.

Arguments

- ***gate_id#***

  A repeatable integer that specifies a gate whose netlist information you are reporting. The value of the gate_id# argument is the unique identification number the tool automatically assigns to every gate within the design during the model flattening process.

- ***instance_name***

  A repeatable string that specifies the name of an instance whose netlist information you are reporting.

- **-All**

  A switch that specifies to report all instances in the current display netlist (including the compacted gates).

- -Display {DEBug | DESign | Data}

  A switch and literal that specify the window containing the instance(s) you are reporting. The window choices are as follows:

DEBug
Specifies the Debug window. This is the invocation default.

DESign
Specifies the Design window.

Data
Specifies the Data window.

- -Full

  A switch that specifies to include the following information for each pin on each reported instance:

  - Pin name
  - Pin type (input or output)
  - Simulated pin data (if appropriate)
  - Gates to which that pin connects

Examples

The following example analyzes a DRC violation (automatically invoking DFTVisualizer in the process and displaying the part of the netlist related to the violation in the Debug window):

set_gate_level design
analyze_drc_violation c3-1

```
//  command: open_visualizer -display debug
//  Note: Gate report now set to clock_cone (clock=/tck).
//  Creating Schematic for 5 instances
```

The DFTVisualizer Transcript window shows the following information for the violation:

```
=============== (Violation ID = c3-1) ================
//  Note: Clock /tck failed rule C3 on input 3 of /reg_enable (76). (C3-1)
//  Note: Source of violation: input 3 of /reg_pstate_2_ (70).
//  Note: Gate report now set to clock_cone (clock=/tck).
Creating Schematic for 5 instances
```

The next example shows the differences between the default and the detailed report for the gate where clock /tck failed the C3 DRC:

report_display_instances /reg_enable

```
// /reg_enable dffr
```

report_display_instances /reg_enable -full

```
// /reg_enable  dffr
//      D      I  (E)  /ix130/Y
//      CLK    I  (C)  /ix473/Y
//      R      I  (-)  /ix475/Y
//      Q      O  (-)  /tri_pin/E
//      QB     O  (-)
```

Related Commands

analyze_drc_violation
open_visualizer
report_gates
set_gate_report

report_drc_rules

Context: all contexts

Mode: all modes

Usage

report_drc_rules [-Fails_summary | -Summary |
rule_id… | *rule_id-occurence#*… | -All_fails]
[{> | >>} *file_pathname*]

C1 Usage:

report_drc_rules **C1** [-EXcluded]

D5 Usage:

report_drc_rules **D5**
[{ [-TYpe {I0 | I1 | IX | T0 | T1 | TX | TLA}…]
[-NOType {I0 | I1 | IX | T0 | T1 | TX | TLA}…]
[-EDge_triggered | -LEvel_sensitive] } | -Summary]
[{> | >>} *file_pathname*]

E5 Usage:

report_drc_rules **E5** [-TIMing_exceptions]

Description

Displays either a summary of DRC violations (fails) or violation occurrence message(s).

This command can display a report in one of two formats:

- Summary report—Lists for each reported design rule, one line of data per rule, the current number of DRC violations (fails), the violation handling, and a brief description of the rule. When you request a summary of D5 violations, the report lists the number of D5 violations of each type (INIT-0, INIT-1, INIT-X, TIE-0, TIE-1, TIE-X, TLA).
- Occurrence report—Lists one or more violation occurrence messages that give details of specific DRC violations

Table 7-25 provides a summary of the available information displayed and the arguments you use to obtain them. Refer to the Arguments subsection for complete details about the arguments.

Table 7-25. Available Information Displayed and Arguments

Desired Display	Rules/Occurrences Covered	Argument
Summary report	Design rules that resulted in violations (fails) during DRC	-Fails_summary
	All design rules	-Summary

Table 7-25. Available Information Displayed and Arguments

Desired Display	Rules/Occurrences Covered	Argument
Occurrence report	Specific rule, specific occurrence	*rule_id-occurence#*
	Specific rule, all occurrences[1]	*rule_id*
	All occurrences	-All_fails

1. Additional D5-specific arguments enable you to further customize the D5 information display.

You can use the set_drc_handling command to change the handling of many of the A (RAM), C (clock), D (data), E (extra), K (EDT), T (trace), and W (timing) rules.

For more information about the design rules, refer to "Design Rule Checking" on page 2135.

Arguments

- -Fails_Summary

  A switch that specifies to display the following for each user-controllable rule that resulted in a violation (fail) during DRC:

  - Rule identification (ID)
  - Number of failures of the rule
  - Current handling status of the rule
  - Brief description of the rule

  This is the default.

Note

This switch does not display anything if there are no rule violations or the tool has not yet performed DRC.

- -Summary

  A switch that specifies to display a summary report that varies depending on whether you are reporting on all design rules or just on the D5 rule. (The latter reporting is available only in Tessent FastScan and Tessent TestKompress.)

  When you report on all rules (report_drc_rules -Summary), the following is reported for each user-controllable rule, whether or not it resulted in a violation (fail) during DRC:

  - Rule identification (ID)
  - Number of failures of the rule
  - Current handling status of the rule
  - Brief description of the rule

When you report on just the D5 rule (report_drc_rules D5 -Summary) in Tessent FastScan or Tessent TestKompress, the tool displays the number of non-scan memory elements of each type (INIT-0, INIT-1, INIT-X, TIE-0, TIE-1, TIE-X or TLA) that resulted in a D5 violation during DRC. Refer to the description of the -Type switch for the meaning of the types. See also the "D5" section for detailed information about the D5 rule.

- *rule_id*

  A repeatable string that specifies the identification literal (ID) of a particular design rule for which you want to display the violations. For information about the design rules and their ID, refer to the appropriate section:

  - RAM Rules (A Rules)
  - BIST Rules (B Rules)
  - Clock Rules (C Rules)
  - Scan Cell Data Rules (D Rules)
  - Extra Rules (E Rules)
  - EDT Finder Rules (F Rules)
  - Flattening Rules (FN, FP, and FG Rules)
  - General Rules (G Rules)
  - EDT Rules (K Rules)
  - Procedure Rules (P Rules)
  - Scannability Rules (S Rules)
  - Scan Chain Trace Rules (T Rules)
  - Power-Aware Rules (V Rules)
  - Timing Rules (W Rules)
  - ICL Extraction Rules (I Rules)
  - ICL Semantic Rules (Semantic Rules)
  - Core Mapping for ATPG and Scan Pattern Retargeting Rules (R Rules)

- *rule_id-occurrence#*

  A repeatable string that specifies the identification literal (ID) of a particular design rule and the violation occurrence for which you want to display the occurrence message. This argument must include the specific design rule ID (*rule_id*), the specific occurrence number of the violation, and the hyphen between them. For example, you can analyze the second violation occurrence of the C3 rule by specifying C3-2. Numbers to occurrences of rule violations are assigned as they are encountered; you cannot change the number assigned to a specific occurrence.

- -All_Fails

  A switch that specifies to display all occurrence messages for all occurrences of rule violations. The displayed information can be lengthy, as it is the same information you would get if you consecutively entered a “report_drc_rules <*rule_id*>” command for each rule that had a violation. Use this switch to output a report of all violation occurrences (most likely to a log file) for later analysis.

- > *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- >> *file_pathname*

  An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

C1-Only Arguments

- **C1**

  A required literal that specifies reporting C1 DRC rule violations.

- -EXcluded

  An optional switch for use only with a C1 violation. Specifying this switch reports the C1 violations that have been excluded from the default C1 list because these C1 violations can be handled by the tool without causing potential mismatch.

D5-Only Arguments

- -TYpe I0 | I1 | IX | T0 | T1 | TX | TLA

  An optional switch and repeatable literal that displays D5 occurrence messages for only the specified type(s) of non-scan sequential elements. The literal choices for the type of element are as follows (the term you will see in occurrence messages for each type is shown in parentheses):

  I0 — If the element is at 0 at the beginning of the first capture cycle and may go to any state during capture. (INIT-0)

  I1 — If the element is at 1 at the beginning of the first capture cycle and may go to any state during capture. (INIT-1)

  IX — If the element’s state is unknown at the beginning of the first capture cycle and may go to any state during capture. (INIT-X)

  T0 — If the element is always at 0 during capture. (TIE-0)

  T1 — If the element is always at 1 during capture. (TIE-1)

  TX — If the element is always at an unknown state during capture. (TIE-X)

  TLA — If the element is always transparent when its clock is at its off state. (TLA)

> **Tip**: Except for TLAs, you can also direct the tool to display information for only those D5 elements that are edge-triggered or level-sensitive. See the -Edge_triggered and -Level_sensitive switch descriptions for details.

- -NOType I0 | I1 | IX | T0 | T1 | TX | TLA

  An optional switch and repeatable literal that specify not to display occurrence messages for the particular type(s) of D5 violations. See the description of the -Type switch for the meaning of the literal choices.

- -EDge_triggered | -LEvel_sensitive

  Optional switches that specify to display D5 occurrence messages either for edge-triggered or level-sensitive elements only. The default (when neither option is specified) is to display information for both edge-triggered and level-sensitive elements.

E5-Only Arguments

- -TIMing_exceptions

An optional switch that specifies to report only on E5 violations due to timing exceptions. In order to use this switch you must first issue a "set_drc_handling -timing_exception_check ON" command in setup mode (see "Example 8" on page 1278).

Example 1

The following example displays a summary of the rules that resulted in violations during an attempted ATPG run:

report_drc_rules

```
C3: #fails=2 handling=warning (clock may capture data affected by its
   captured data)
C5: #fails=1 handling=error (clock is connected to multiple ports of same
   latch)
C7: #fails=19 handling=warning (scan cell capture ability check)
C8: #fails=2 handling=warning (PO connected to a clock line)
C9: #fails=2 handling=warning (PO connected to a clock line gated by scan
   cell that uses same clock)
D5: #fails=23 handling=warning (non-scan memory element)
D6: #fails=22 handling=warning (non-transparent non-scan latches)
D7: #fails=22 handling=warning (stable high edge-triggered clock ports)
```

Example 2

The following example displays the occurrence message for the two C3 violations, and the first C7, and first D7 violation reported in the preceding example:

report_drc_rules c3 c7-1 d7-1

```
// Warning: Clock /sgst failed rule C3 on input 3 of /sp_b_i0.latch
   (1501). (C3-1)
// Source of violation: input 3 of /sp_c_i1.slave (1482).
// Warning: Clock /sgst failed rule C3 on input 3 of /sp_c_i0.latch
   (1527). (C3-2)
```

```
// Source of violation: input 3 of /sp_c_i1.slave (1482).
// Warning: Clock input 5 of /c8.master (1495) cannot capture data
   with single clock on. (C7-1)
// Warning: Flipflop /FF1 (103) has clock port set to stable high. (D7-1)
```

Example 3

The following example changes the handling of data rule 7 (D7) from warning to error and also specifies execution of a full test generation analysis when performing the rules checking for the clock (C) rules:

set_drc_handling d7 error atpg_analysis
set_system_mode analysis

```
//-------------------------------------------------------------
//Begin scan chain identification process, memory elements=8.
//-------------------------------------------------------------
// Reading group test procedure file /user/design/tpf.
// Simulating load/unload procedure in g1 test procedure file.
// Chain = c1 successfully traced with scan_cells = 8.
// Error: Flipflop /FF1 (103) has clock port set to stable high.(D7-1)
// Error: Rules checking unsuccessful, cannot exit SETUP mode.
```

Example 4

The following example displays the occurrence message for the D7 violation:

report_drc_rules d7-1

```
//Error: Flipflop /FF1 (103) has clock port set to stable high. (D7-1)
```

Example 5

The following example displays a summary of the non-scan memory elements that resulted in D5 rule violations:

report_drc_rules d5 -summary

```
//  ---------------------------------------------------------------------
